Properties of radiation

Where x-rays come from

review of relativity

bending magnet radiation

undulator radiation

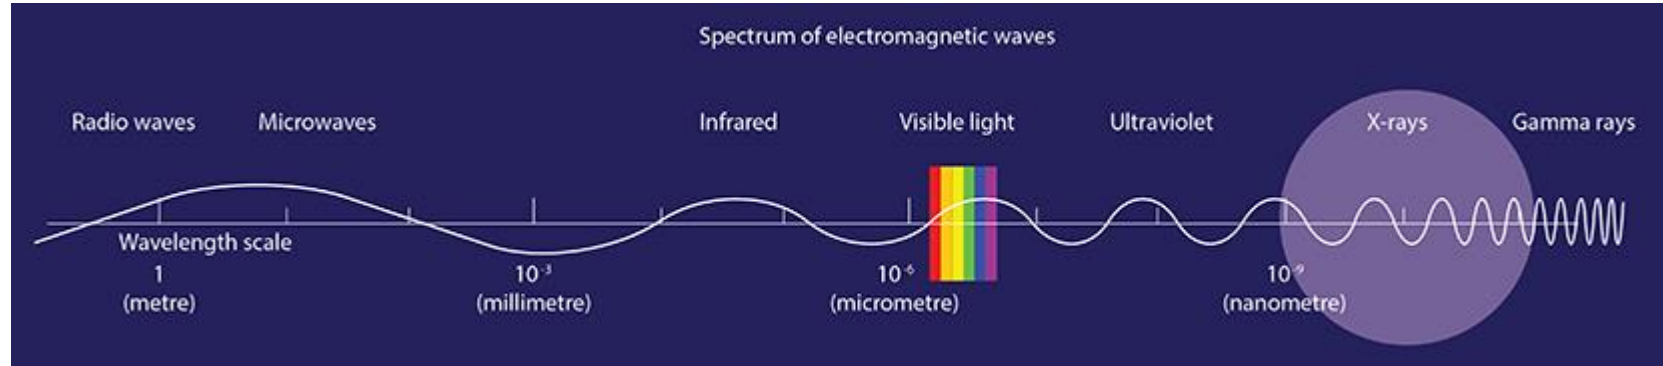

Particle accelerators:

how to store electron beams

what is the distribution of the electron beam

ESRF upgrade: EBS

Spectrum of electro-magnetic radiation

$$f = c / \lambda$$

$$E_{\gamma} = h f$$

$$c = 299792458 \text{ m/s}$$

$$h = 4.135667517 \times 10^{-15} \text{ eV s}$$

λ is the photon wavelength

f is the photon frequency

E_{γ} is the photon energy

c is the speed of light

h is the Planck constant

E_{γ} for X-rays is
about 1-100 keV

PROPERTIES OF RADIATION

Flux of radiation:
number of photons per second

Brightness of radiation:
flux at a specific wavelength divided by
source size and divergence

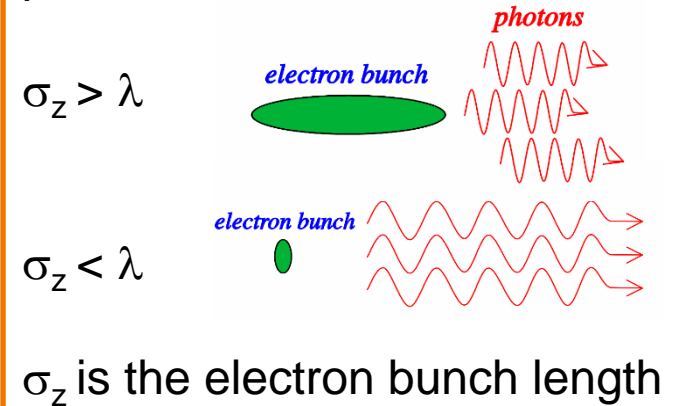

**Low brightness: low
photon density on sample**

**High brightness: high
photon density on sample**

Coherence of radiation:
are the photons produced in
phase or not?

Polarization of radiation:
directionality of radiation field
linear, circular partial/full
polarization

Synchrotron light sources give some control over all these properties

WHERE X-RAYS COME FROM

Accelerating charged particles emit electro-magnetic radiation

Maxwell's equations:

$$\nabla \cdot \mathbf{E} = 4\pi\rho$$

$$\nabla \cdot \mathbf{B} = 0$$

$$\nabla \times \mathbf{E} = -\frac{1}{c} \frac{\partial \mathbf{B}}{\partial t}$$

$$\nabla \times \mathbf{B} = \frac{1}{c} \left(4\pi\mathbf{J} + \frac{\partial \mathbf{E}}{\partial t} \right)$$

Non-relativistic Larmor formula:

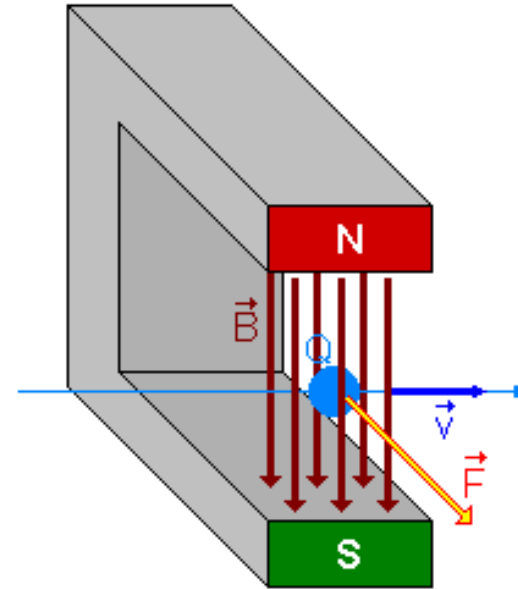

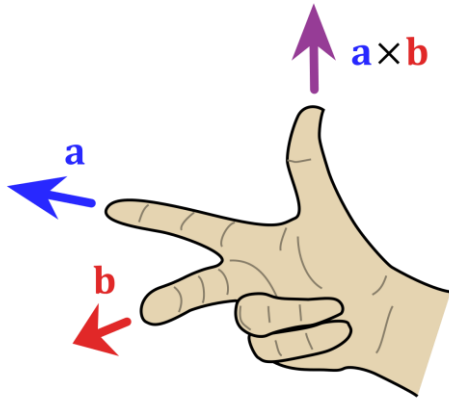

$$P = \frac{q^2 a^2}{6\pi\epsilon_0 c^3}$$

P is the power radiated
q is the electric charge
a is the acceleration

LORENTZ FORCE

We can move charged particles using the Lorentz force

$$\vec{F} = q \cdot (\vec{E} + \vec{v} \times \vec{B})$$

The force, and so the acceleration, is perpendicular to the particle velocity. Particles travel on an arc of circumference inside the dipole magnets.

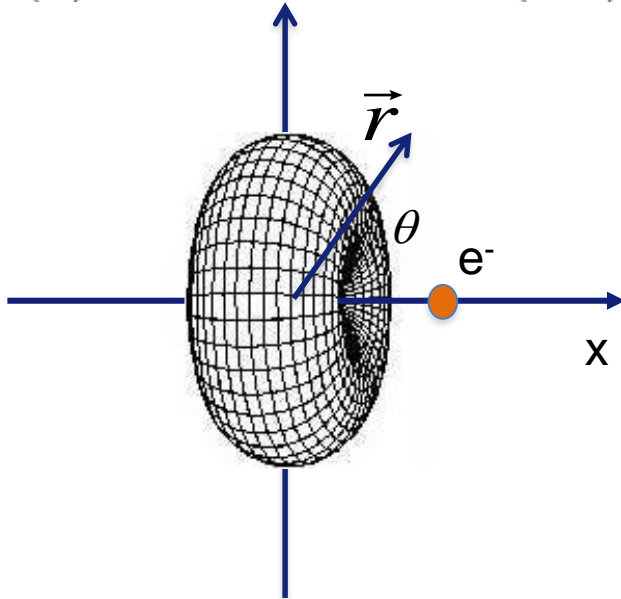

SINGLE PARTICLE IN A HARMONIC OSCILLATOR

Charge oscillating along x

$$x(t) = A \cos(\omega t)$$

$$v(t) = -A\omega \sin(\omega t)$$

$$a(t) = -A\omega^2 \cos(\omega t)$$

It emits radiation in all directions

$$\langle S \rangle \propto \frac{\sin^2 \theta}{r^2} \hat{r}$$

S is the Poynting vector (energy per unit of time and surface)

Frequency of radiation is

$$f = \frac{\omega}{2\pi}$$

Wavelength of radiation is

$$\lambda = \frac{c}{f}$$

$$\beta = \frac{v}{c}$$

$$\gamma = \frac{1}{\sqrt{1 - \beta^2}}$$

$c = 299792458$ m/s
is the speed of light

$$\text{Total energy } E = \gamma mc^2$$

$$\text{Kinetic energy } E_k = (\gamma - 1)mc^2$$

$$E_k \rightarrow \frac{1}{2}mv^2, \text{ for } \beta \ll 1$$

For an electron with energy E :

$$\gamma = \frac{E}{mc^2} = \frac{E}{510998.9461 \text{ eV}}$$

$$m_{e^-} = 510998.9461 \frac{\text{eV}}{c^2}$$

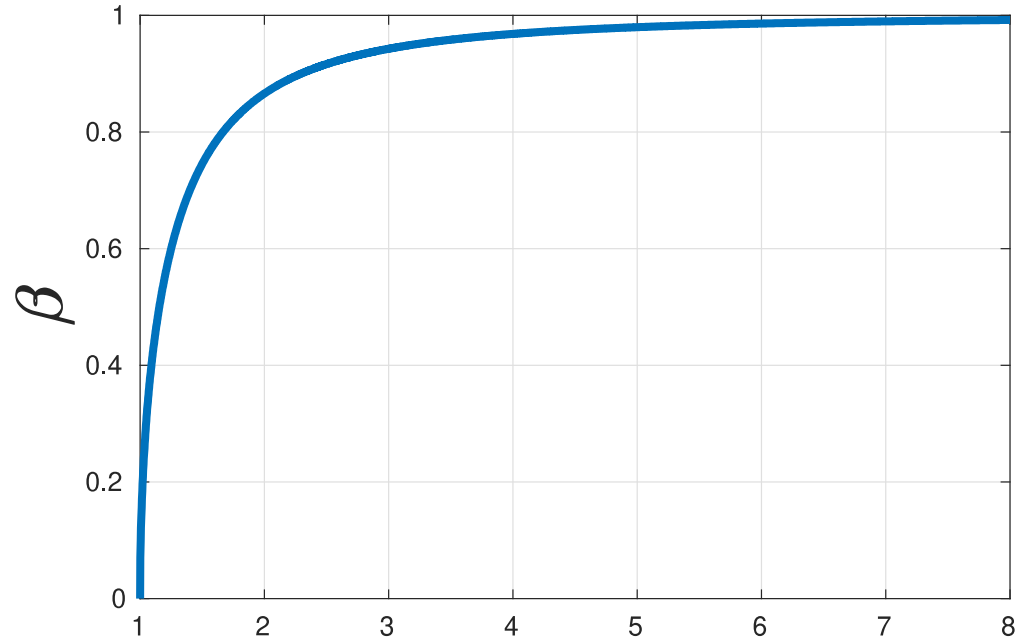

BRIEF REVIEW OF RELATIVITY

β is always less than 1

Velocity is almost c already for $\gamma \sim 5$

At ESRF $\gamma = 11800$

Increasing the electron energy from few MeV to 6 GeV does not change much the velocity.

However, there are two effects as gamma gets large:

- length contraction
- time dilation

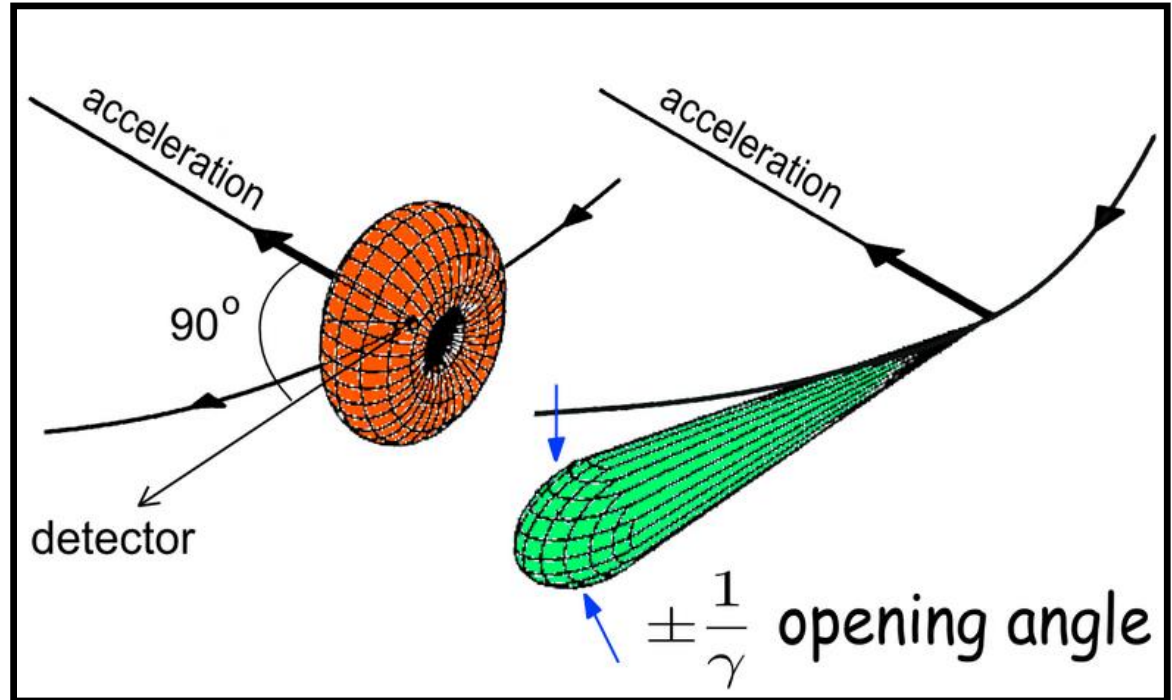

$$L = L_0 \sqrt{1 - \frac{v^2}{c^2}} = \frac{L_0}{\gamma}$$

γ

$$T = \frac{T_0}{\sqrt{1 - \frac{v^2}{c^2}}} = T_0 \gamma$$

RADIATION EMITTED IN RELATIVISTIC CASE

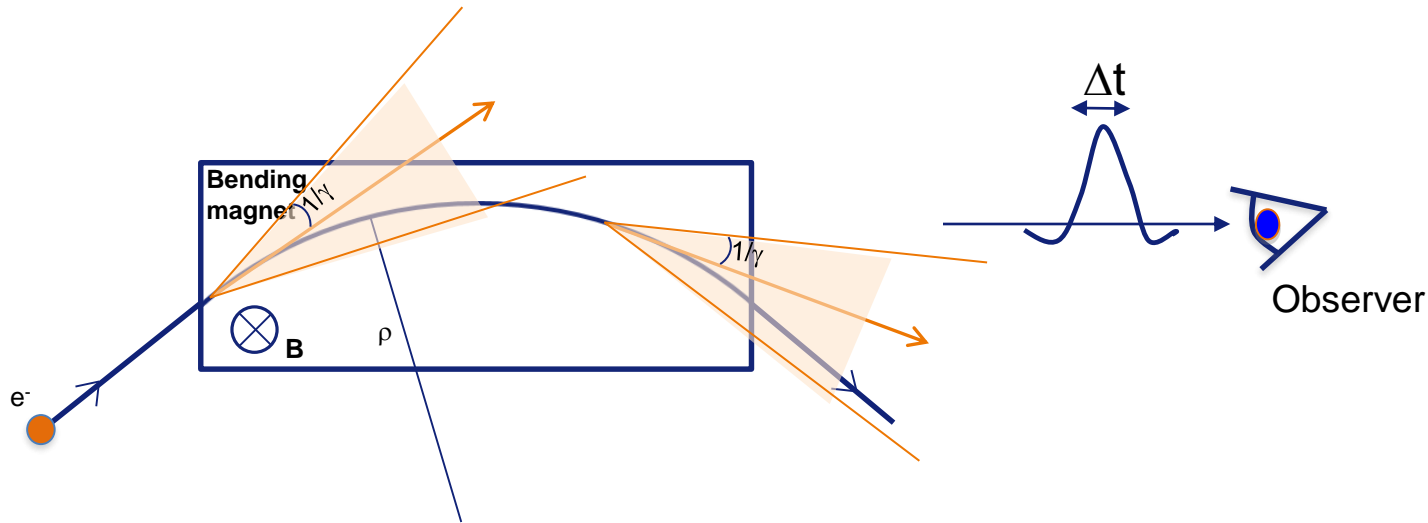

If the charged particle is moving very fast, the radiation is emitted in a cone, with aperture $1/\gamma$

BENDING MAGNET RADIATION: TYPICAL ENERGY

What is the **typical energy** of the radiation from a bending magnet?

First, let's see for how long an observer would see the radiation produced by an ultra-relativistic electron in a bending magnet.

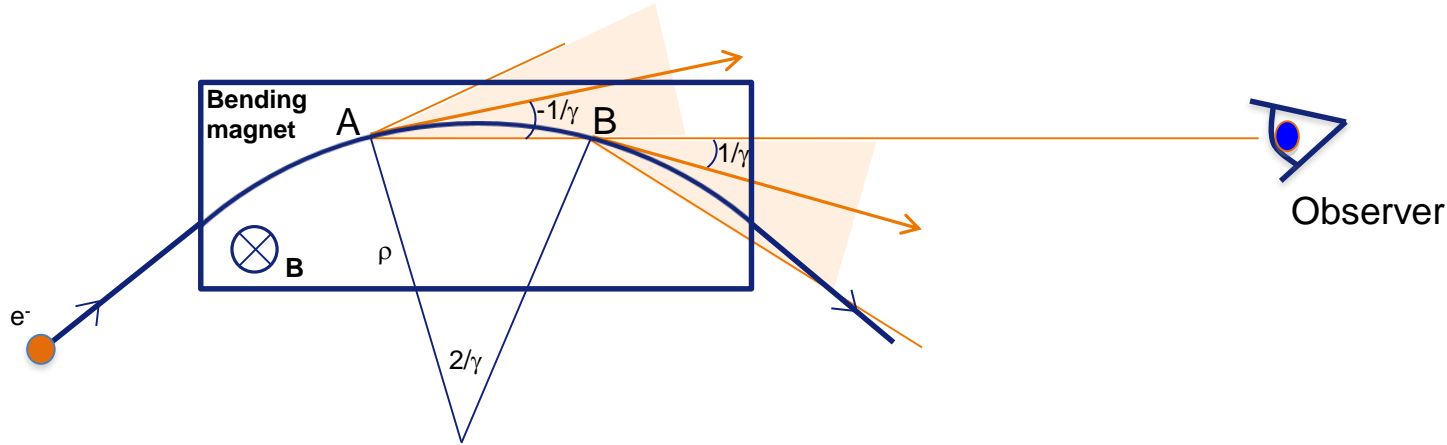

From the length Δt of the pulse we can estimate a typical energy E_{typ} :

$$f_{\text{typ}} = 1/\Delta t$$

$$E_{\text{typ}} = h f_{\text{typ}}$$

BENDING MAGNET RADIATION: TYPICAL ENERGY

How long does the observer see the radiation produced by an ultra-relativistic electron in a bending magnet?

The observer will first see the radiation produced in the point A, with an angle $-1/\gamma$. The last photon seen will be the one produced in B with an angle $+1/\gamma$. The observer will therefore see radiation for an amount of time equal to the difference between the time needed by the electron to go from A to B and the time needed by the photon to go from A to B.

$$\Delta t = t_{ABe^-} - t_{AB\gamma} = \frac{\overline{AB}}{\beta c} - \frac{\overline{AB}}{c} = \frac{2\rho}{\gamma\beta c} - \frac{2\rho \sin(1/\gamma)}{c}$$

$$\sin(\theta) \simeq \theta - \frac{\theta^3}{6}, \quad \text{for } \theta \ll 1 \quad \gamma \gg 1, \quad 1 - \beta \simeq \frac{1}{2\gamma^2}$$

$$\Delta t \simeq \frac{2\rho}{\beta\gamma c} - \frac{2\rho}{c} \left(\frac{1}{\gamma} - \frac{1}{6\gamma^3} \right) = \frac{2\rho}{\beta\gamma c} \left(1 - \beta + \frac{\beta}{6\gamma^2} \right) = \frac{4}{3} \frac{\rho}{c\gamma^3}$$

$$\omega_{typ} = \frac{2\pi}{\Delta t} = \frac{3\pi c\gamma^3}{2\rho}$$

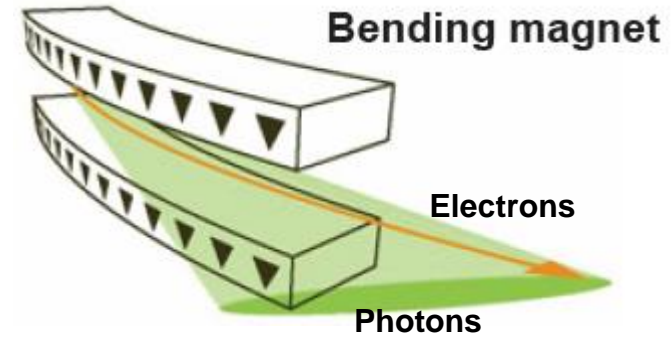

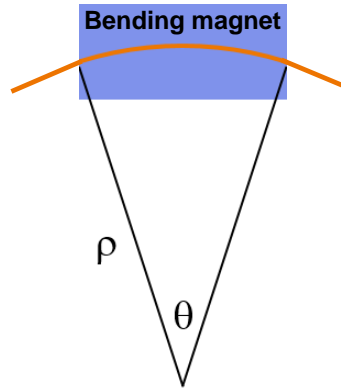

$$E_{typ} = \hbar\omega_{typ} = \frac{3\pi}{2} \frac{\hbar c}{\rho} \gamma^3$$

BENDING MAGNET RADIATION

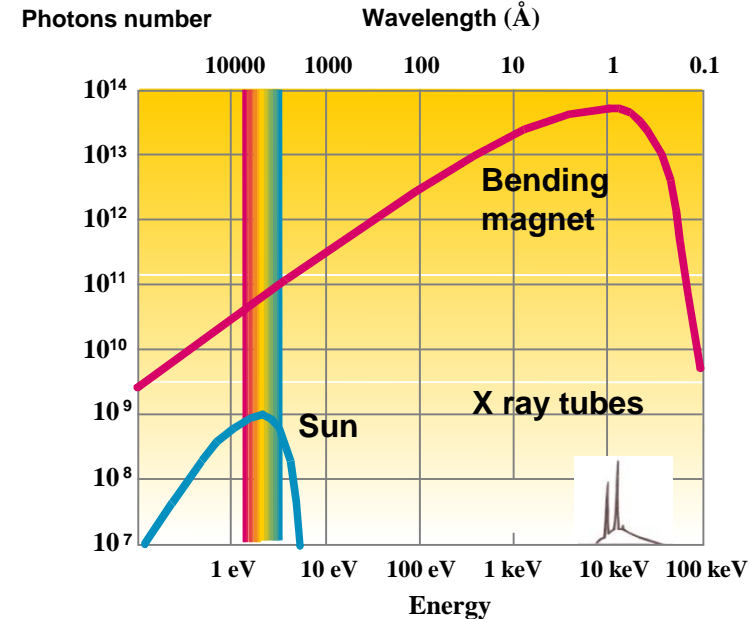

Power emitted by an ultra-relativistic particle in a bending magnet

$$P = \frac{1}{6} \frac{e^2 c}{\pi \epsilon_0} \frac{1}{\rho^2} \left(\frac{E}{mc^2} \right)^4$$

ρ is the radius of curvature

Radiation spectrum

Critical photon energy:
half of the power is
radiated at larger energy
and half at lower

$$\epsilon_c = \frac{3}{2} \frac{\hbar c}{\rho} \gamma^3$$

BENDING MAGNET RADIATION

Parameters for the EBS bending magnet beamlines

$$E = 6 \text{ GeV}$$

$$\gamma = 11800$$

$$\rho = 23.3 \text{ m}$$

$$\varepsilon_c = 21 \text{ keV}$$

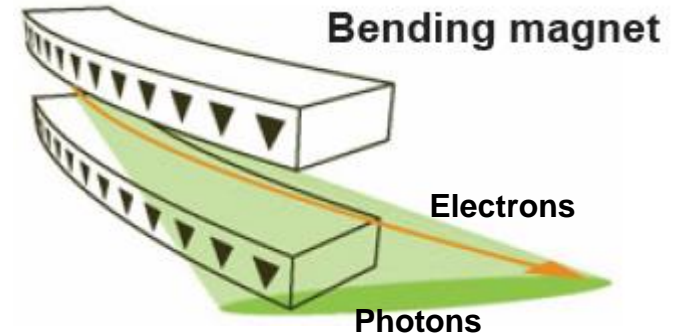

If we put protons instead of electrons?

$$m_p = 938 \text{ MeV}/c^2$$

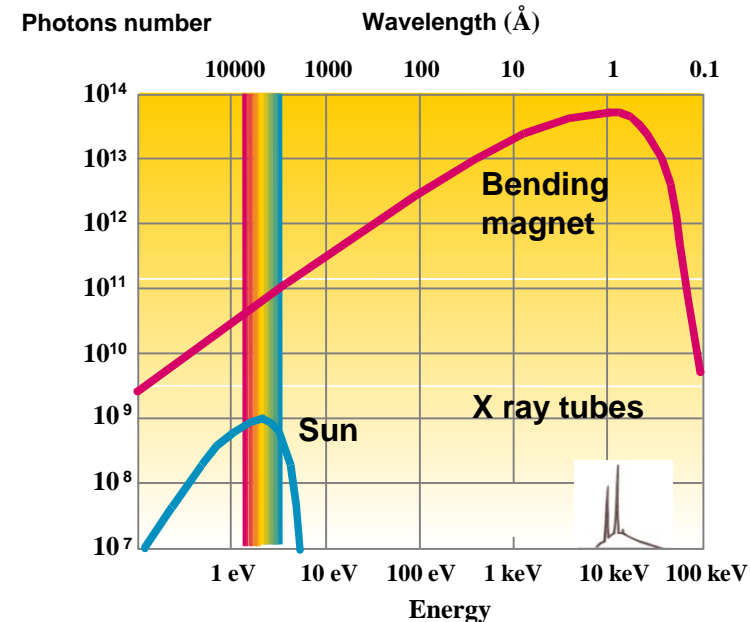

$$m_e = 0.511 \text{ MeV}/c^2$$

Radiated power would be 10^{13} times smaller

$$\varepsilon_c = 3.3 \text{ } \mu\text{eV}$$

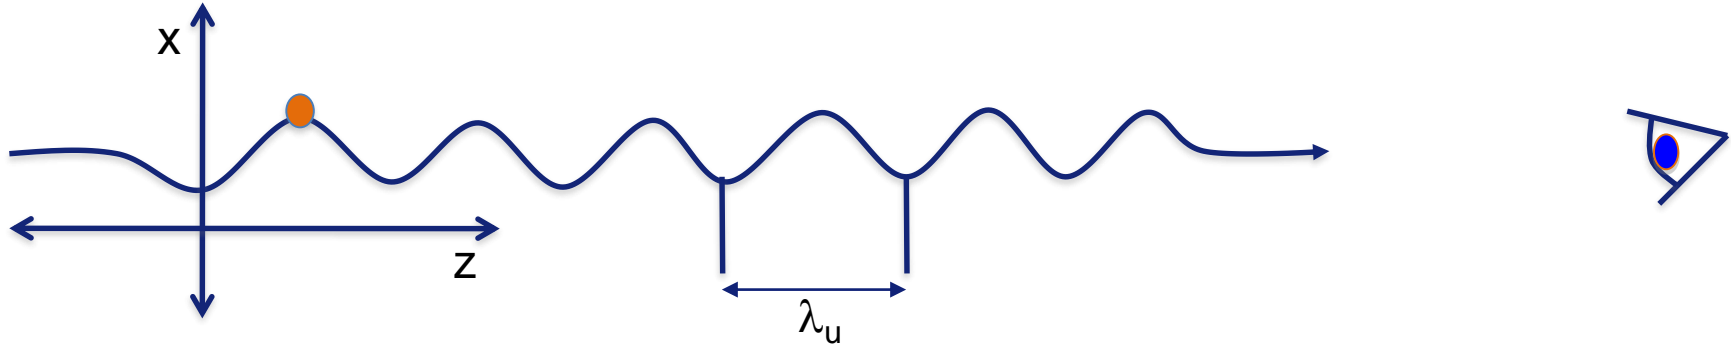

Radiation spectrum

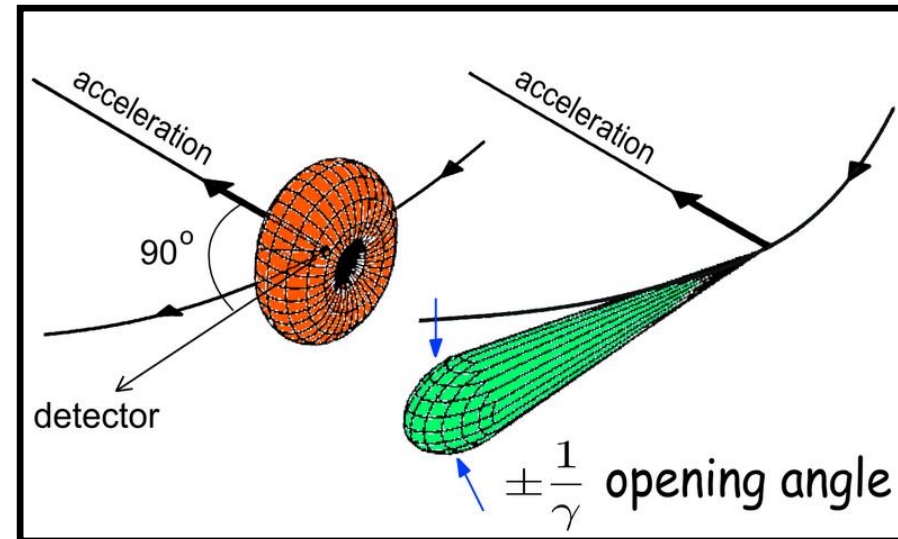

UNDULATOR RADIATION

Consider now a single charge oscillating on x and also moving along z direction

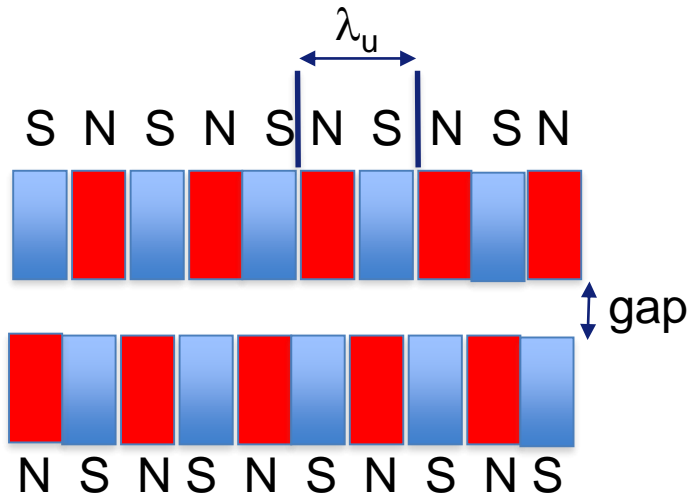

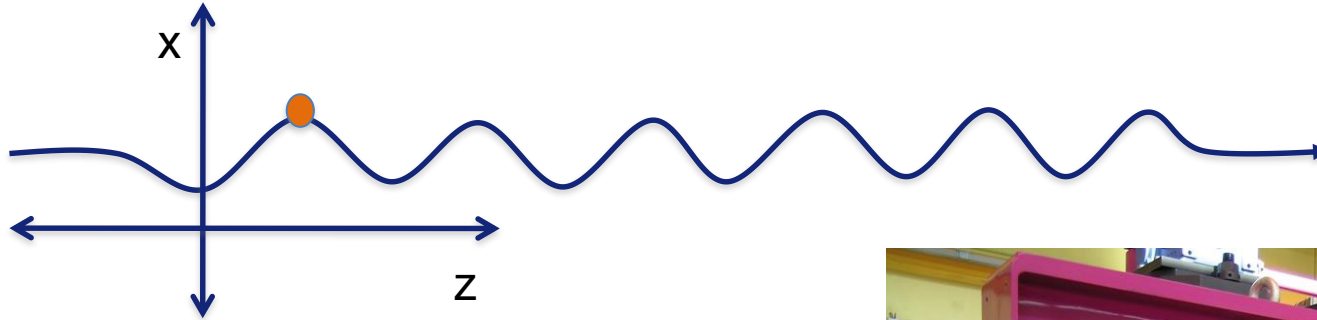

1. The wavelength is shifted by Doppler effect and, in case of relativistic speed, there is a time dilation effect. $\lambda = \frac{\lambda_u}{\gamma^2}$
2. Pattern of radiation gets distorted from motion. For high energy gets bent into cone of angle $1/\gamma$.

UNDULATOR RADIATION

We can build magnets to have this kind of trajectory inside: undulators and wigglers

Undulator at ESRF

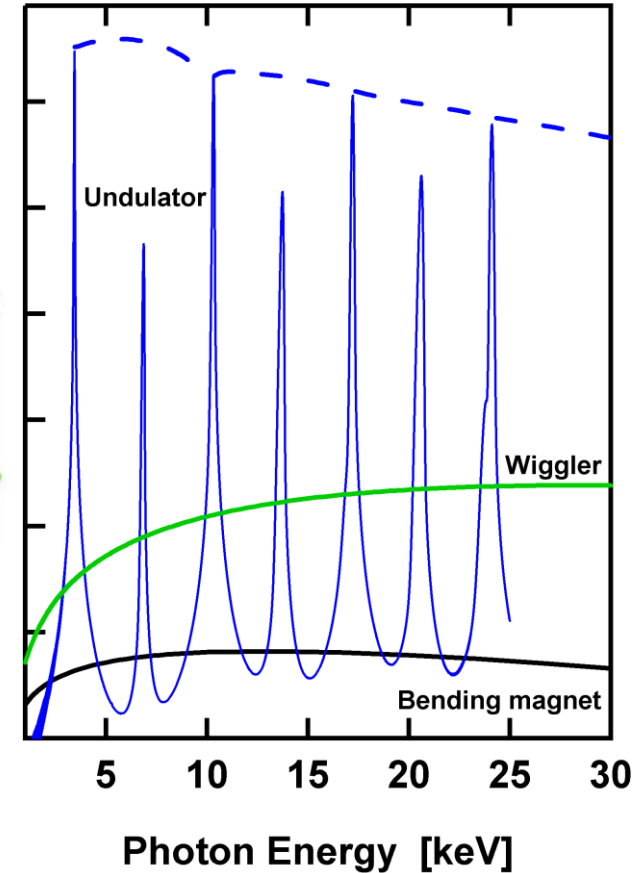

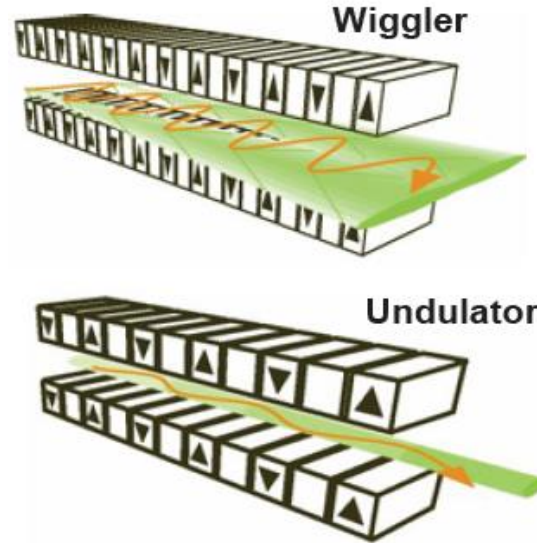

UNDULATOR RADIATION

Undulator parameter K

$$K = \frac{eB_0\lambda_u}{2\pi mc}$$

If K is large ($K \gg 1$), the device is no longer called undulator, but wiggler.

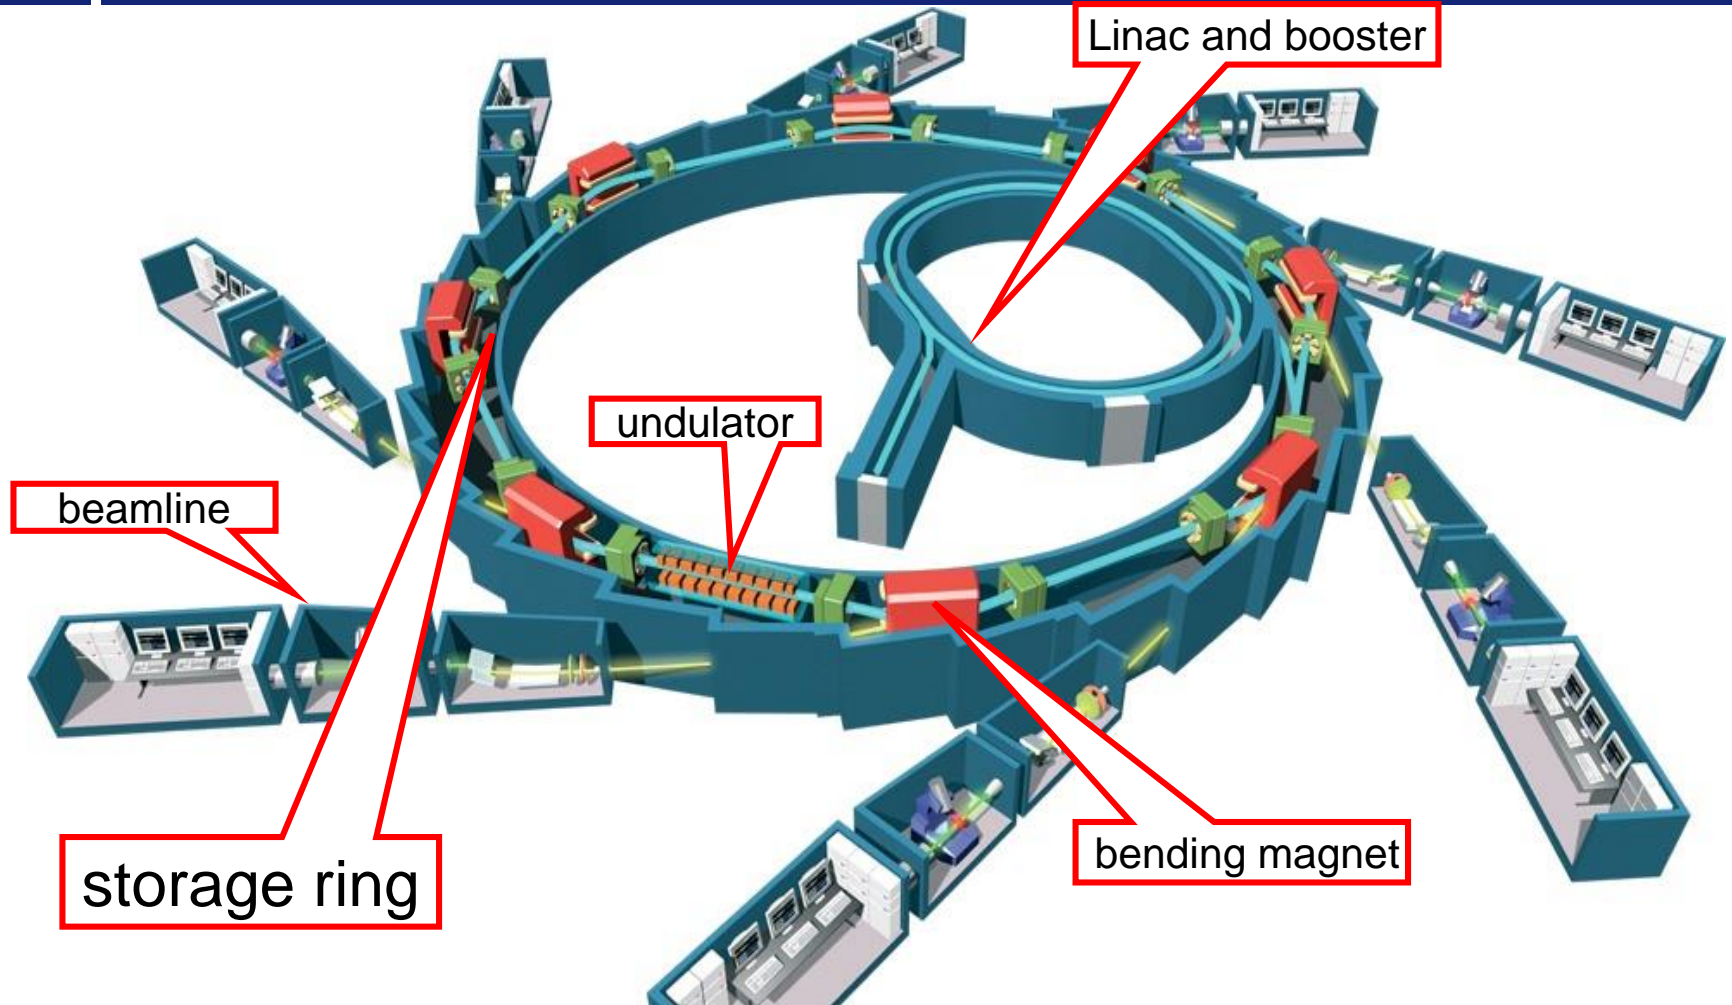

K can be changed by varying the gap of the undulator.

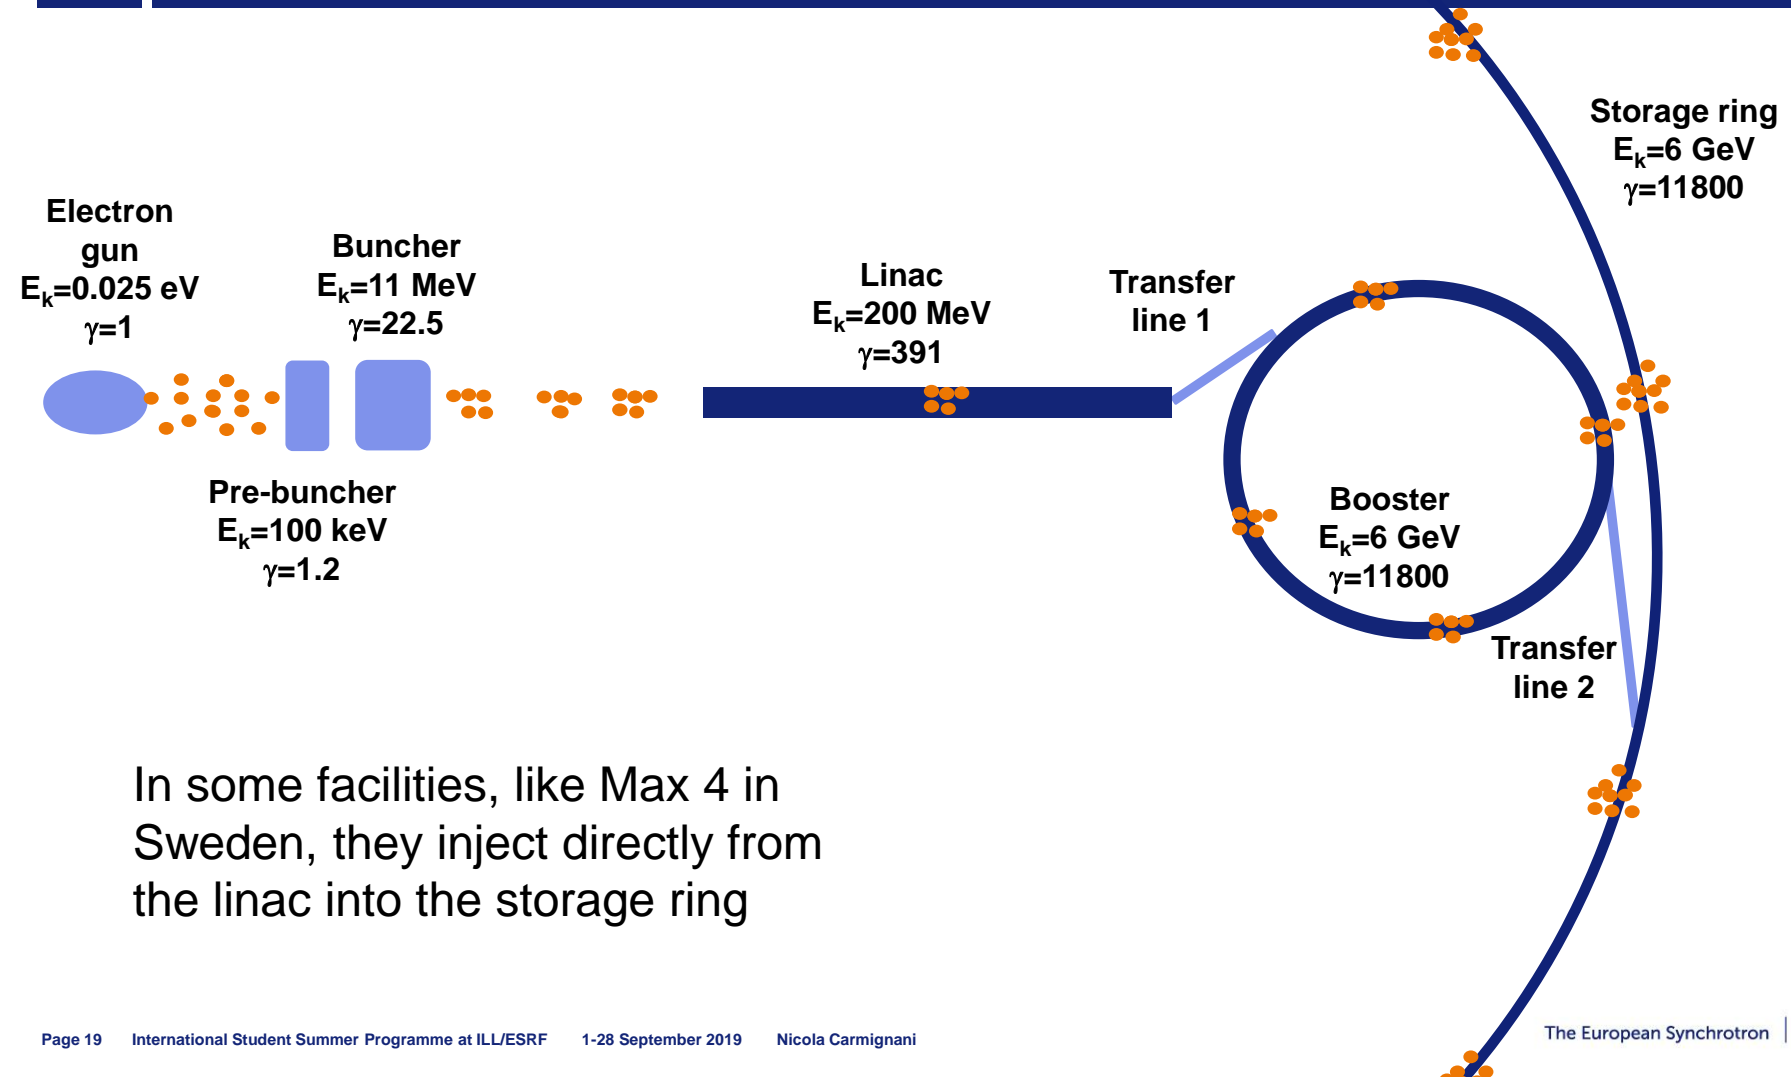

Fundamental undulator wavelength λ_1

$$\lambda_1(\theta) \approx \frac{\lambda_u}{2\gamma^2} \left(1 + \frac{K^2}{2} + (\gamma\theta)^2 \right)$$

HOW DOES A STORAGE RING WORK: MAGNETS

128 at ESRF

Bending magnets (dipoles)

have uniform constant vertical magnetic field

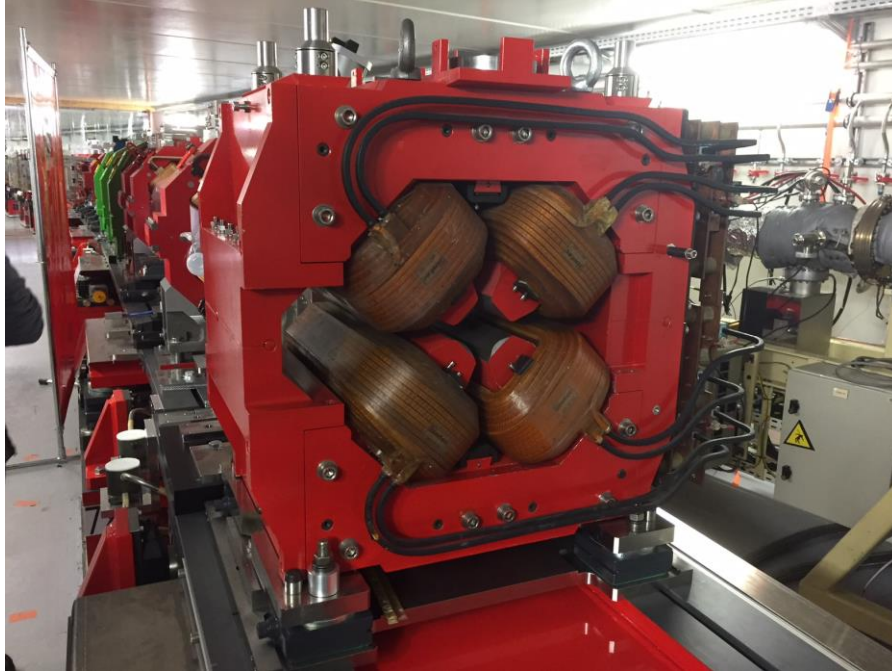

$$B_y = B_0$$

They bend the beam and they define the circular trajectory.

At ESRF, each of the 5 pieces have a different magnetic field.

HOW DOES A STORAGE RING WORK: MAGNETS

512 at ESRF

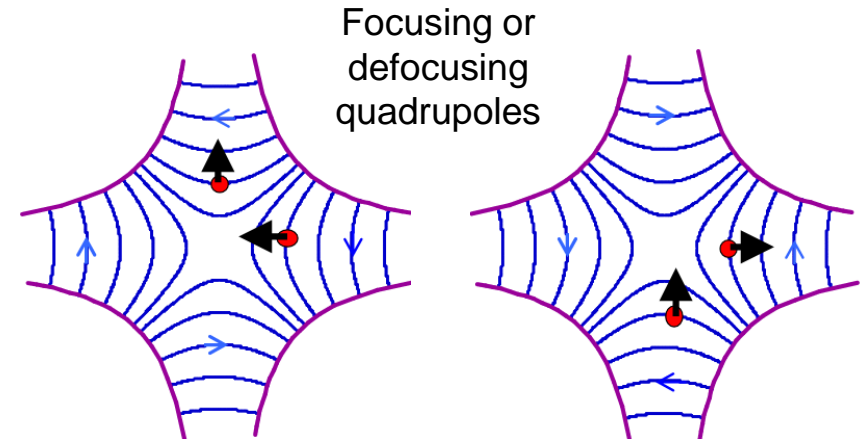

Quadrupoles:

magnetic field is linear with the distance from the center

$$B_y = K_1 x$$

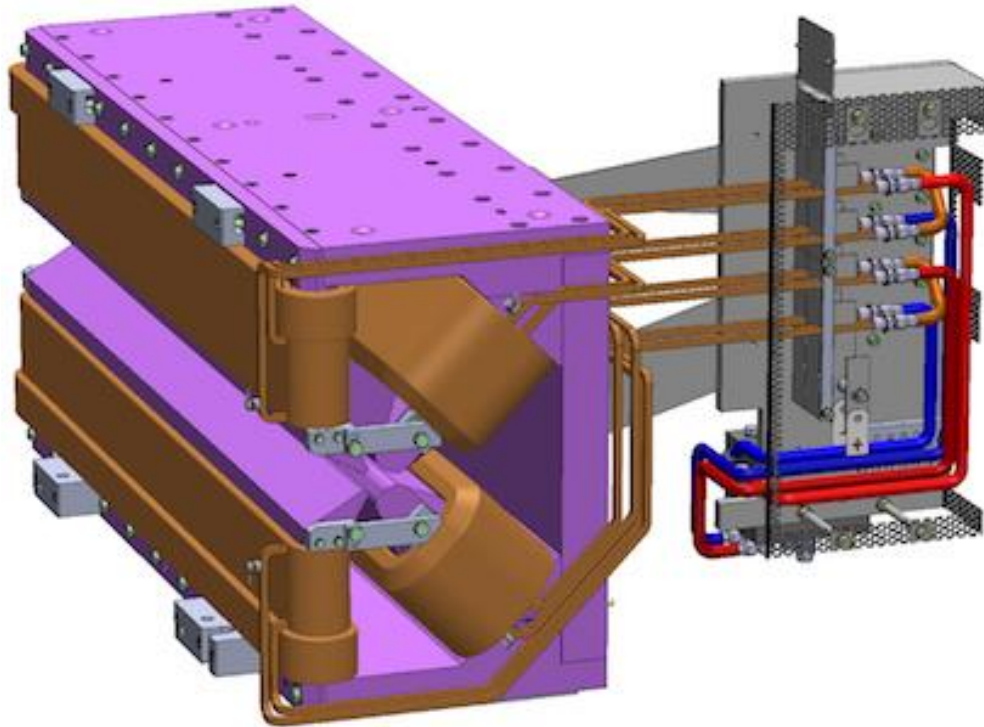

They are used to focus the beam.

There are focusing or defocusing quadrupoles: if they focus horizontally, they defocus in vertical and vice versa (like astigmatic lenses in optics).

HOW DOES A STORAGE RING WORK: MAGNETS

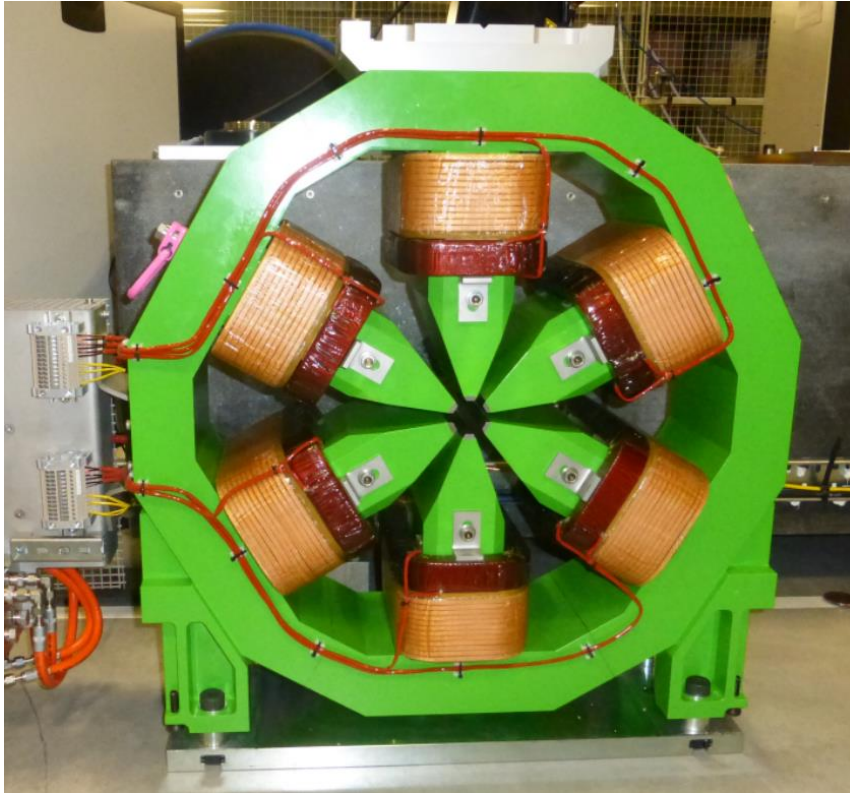

96 at ESRF

Dipole-Quadrupoles (DQ):
magnetic field is the one of a dipole plus the one of a quadrupole:
 $B_y = B_0 + K_1 x$
They are used to bend and focus the beam.

HOW DOES A STORAGE RING WORK: MAGNETS

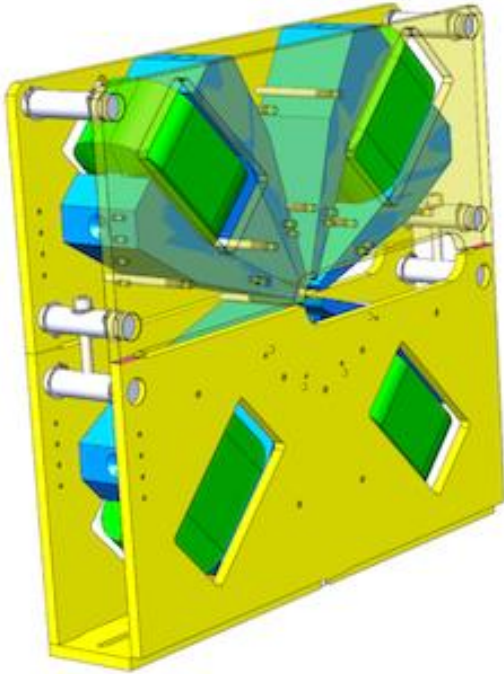

192 at ESRF

Sextupoles: magnetic field is quadratic with the distance from the center
 $B_y = K_2 x^2$
They are used to correct chromatic effects.

If correctly placed, they focus more the particles with higher energy and less the particles with lower energy. They correct chromatic effects.

HOW DOES A STORAGE RING WORK: MAGNETS

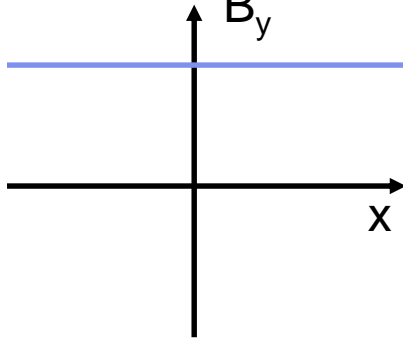

Octupoles:
the field is cubic
with distance:
 $B_y = K_3 x^3$

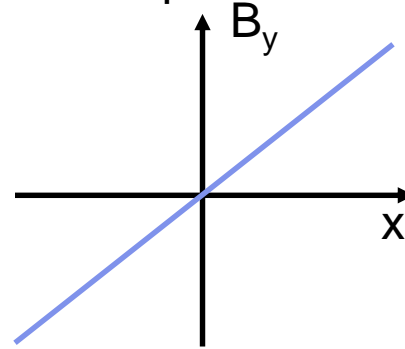

Correctors:
they can provide
horizontal dipole
field, vertical
dipole field,
quadrupolar
field.

Quadrupole

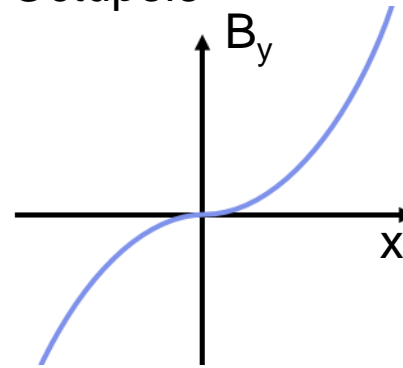

Dipole-Quadrupole

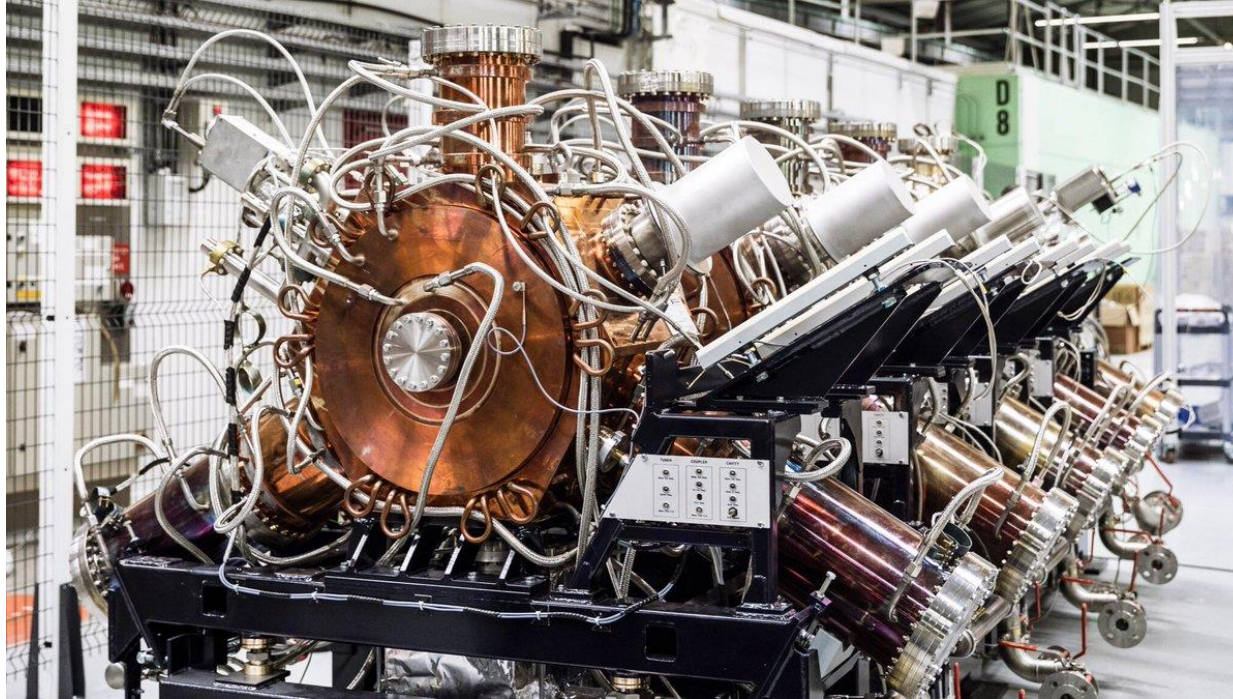

Sextupole

Octupole

HOW DOES A STORAGE RING WORK: ACCELERATING RF CAVITIES

Most of the ESRF energy use (around 1.5 MW of power) is in these cavities

Radio Frequency cavities

They give to the beam the energy lost in synchrotron radiation and they provide longitudinal focusing.

They produce an oscillating longitudinal electric field

$$V(t) = V_{\text{RF}} \sin(h\omega_0 t)$$

$$\omega_0 = 2\pi f_{\text{rev}}$$

At ESRF:

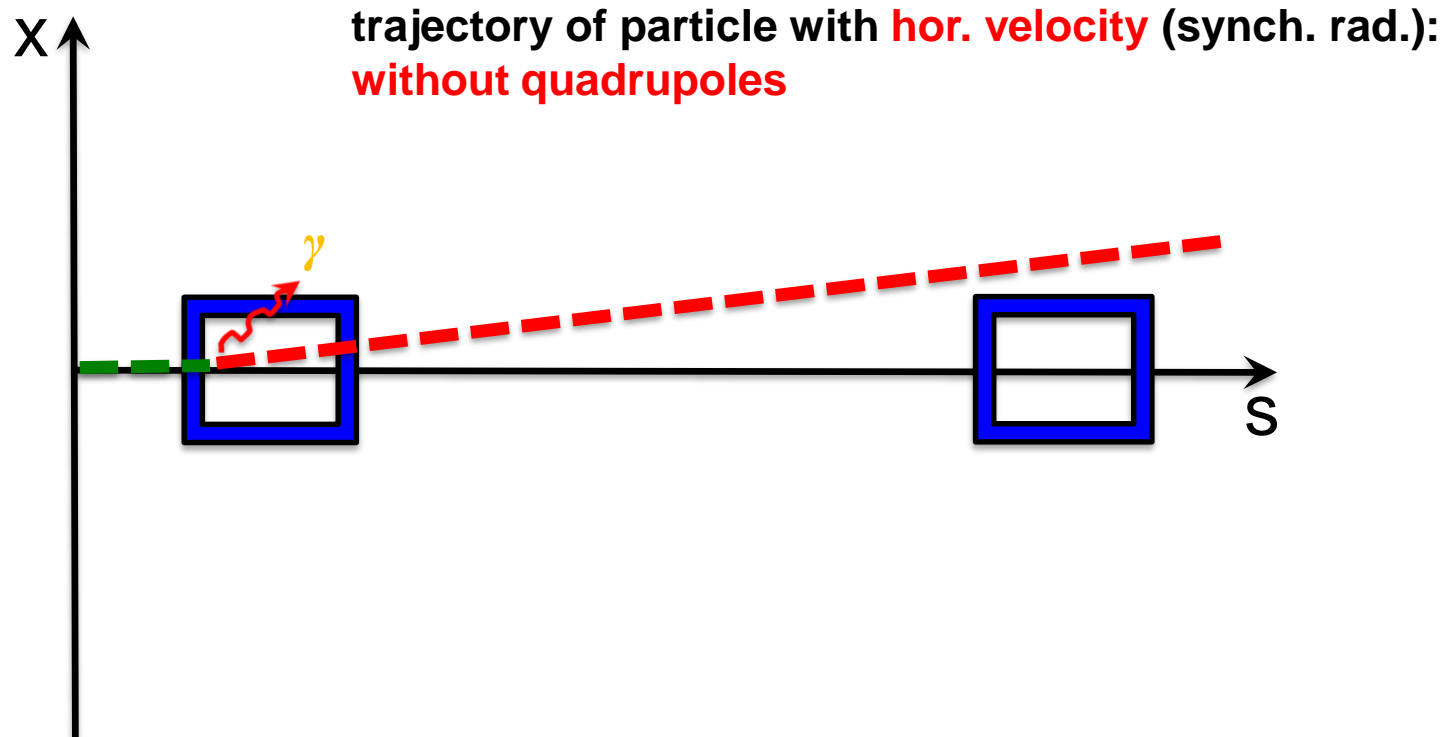

$$f_{\text{rev}} = 355 \text{ kHz}$$

$$h = 992$$

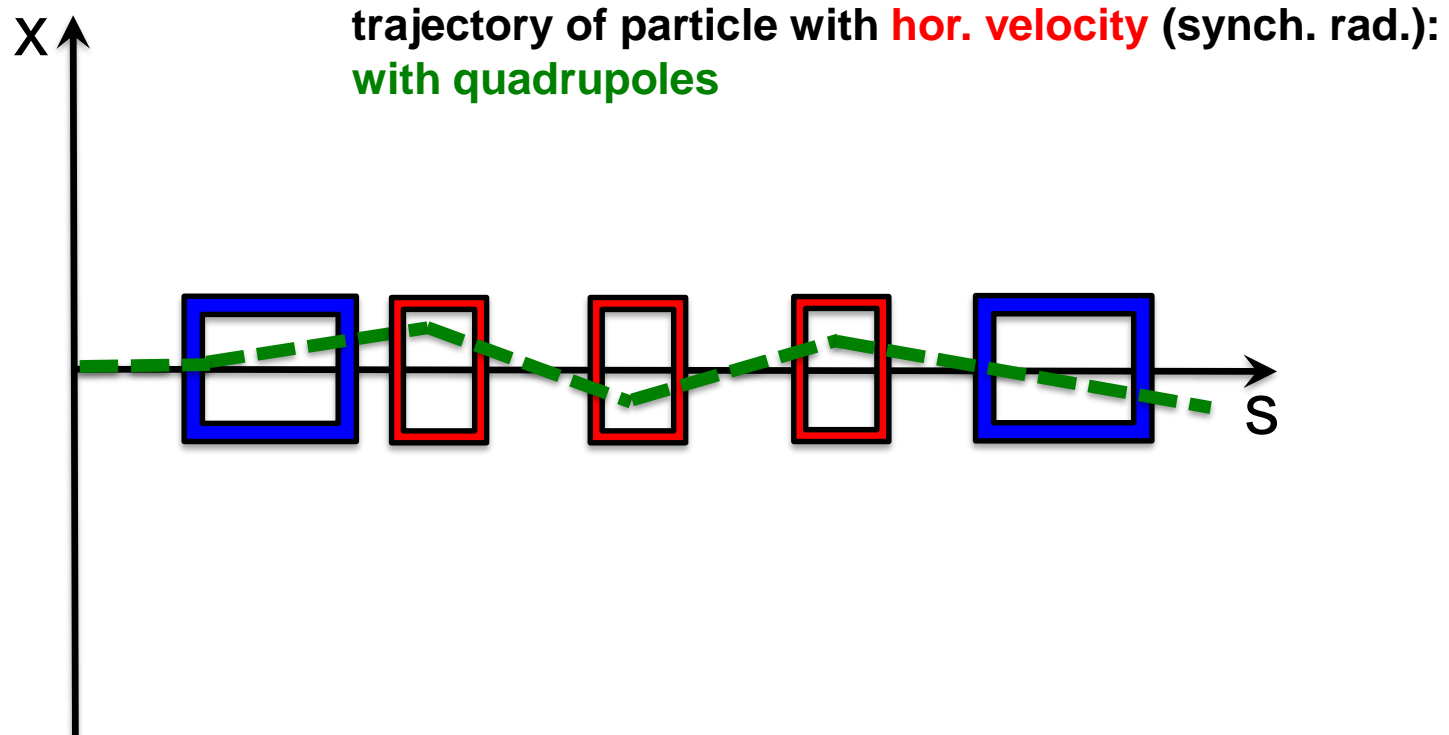

$$f_{\text{RF}} = hf_{\text{rev}} = 352 \text{ MHz}$$

$$V_{\text{RF}} = 6.5 \text{ MV}$$

DISTRIBUTION OF THE STORED ELECTRONS

DISTRIBUTION OF THE STORED ELECTRONS

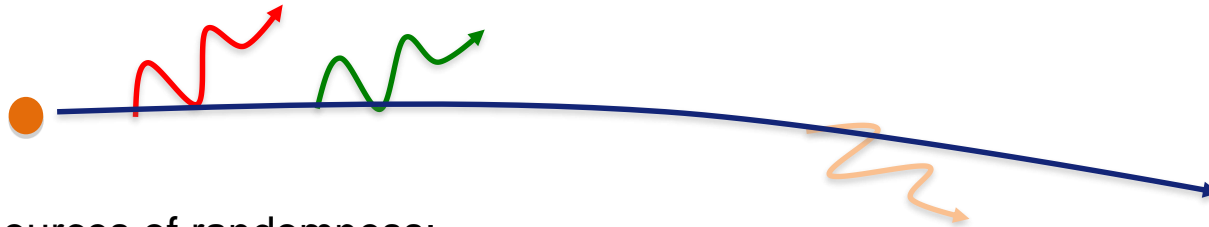

Energy oscillations
(**synchrotron oscillations**)
and radiation damping.

So what defines the size of
the electron beam?

DISTRIBUTION OF THE STORED ELECTRONS

Question: if we have radiation damping, why isn't the electron beam size zero?

Answer: because of the graininess of the photon emission

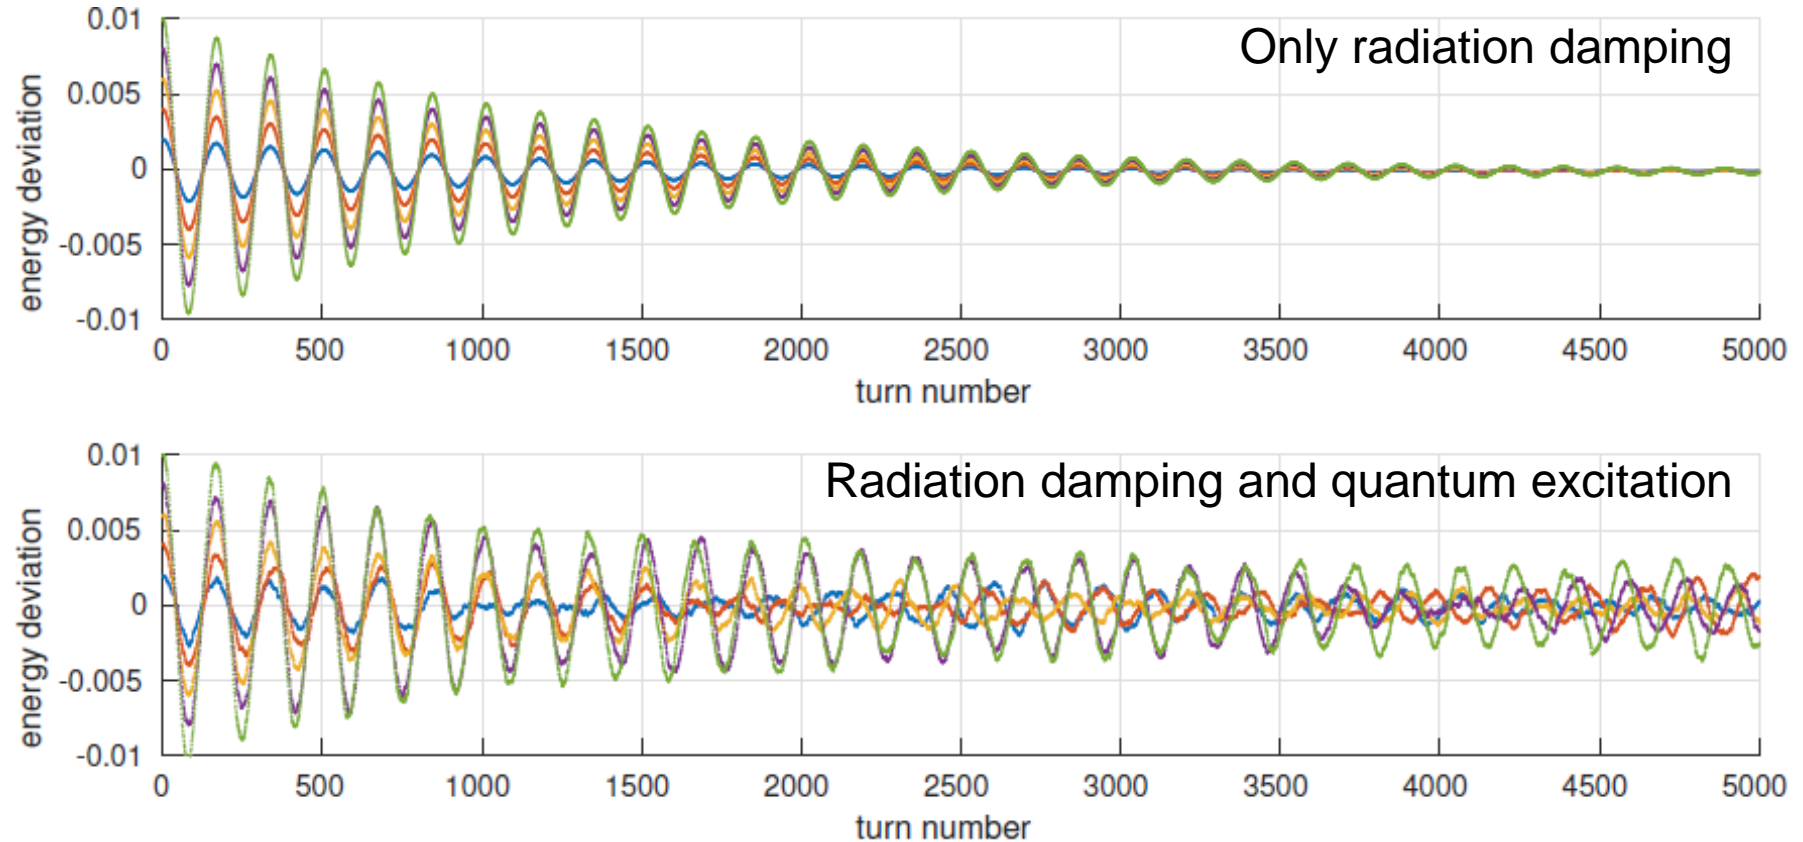

Two sources of randomness:

- emission time of photons: Poisson process
- energy of the photon emitted

This causes a diffusion process in energy, that is converted to a transverse diffusion by the dipoles (higher energy electrons are bended less than lower energy ones).

For ESRF, each electron emits only about 800 photons per turn, about 1 photon emitted per meter! (approx. 12 photons per dipole)
Energy loss per turn $U_0 = 4.88$ MeV

DISTRIBUTION OF THE STORED ELECTRONS

Results of damping and diffusion

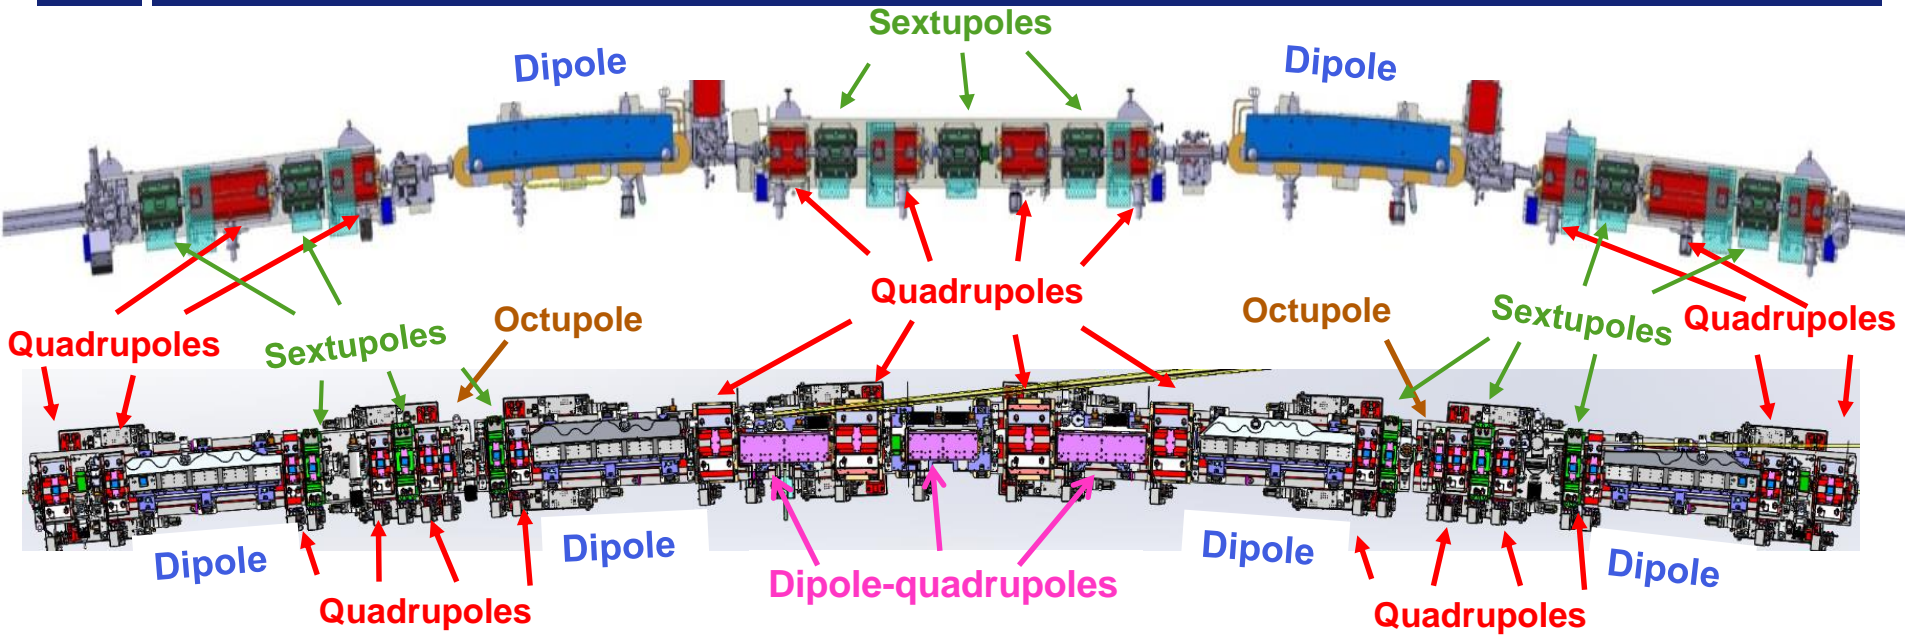

The electron beam reaches a unique Gaussian distribution, independent of how one injects into the ring.

This is a major difference between electron synchrotrons and proton synchrotrons (e.g. LHC)

By careful choice of where the dipoles and quadrupoles are, one can reduce the size of this equilibrium beam size (emittance = beam size in phase space).
So called “low emittance ring design”.

In fact, due to developments in lattice design, ESRF has completely replaced the storage ring in 2019 to reduce the electron beam emittance. 4nm rad \rightarrow 130 pm rad

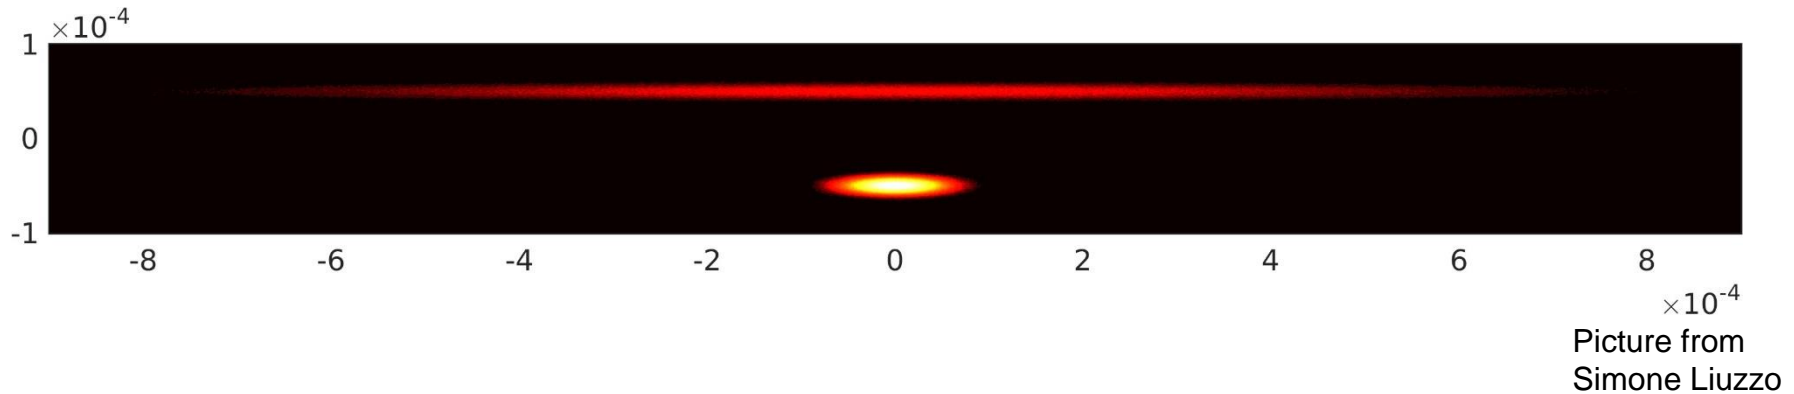

ESRF EBS UPGRADE

The ESRF **Extremely Brilliant Source** (EBS) will have 31 magnets per cell instead of 17
Free space between magnets (total for one cell):
3.4m instead of **8m** today!

Magnet type	ESRF	ESRF EBS
Dipoles	64	128
Dipole-Quadrupoles	0	96
Quadrupoles	256	512
Sextupoles	224	192
Octupoles	0	64
Correctors	0	96

x-y beam distribution for old and new machine.

Electron beam horizontal emittance will be reduced by a factor 30 and brightness will then increase by the same factor.

$$\varepsilon_{\text{ESRF}} = 4 \text{ nm rad}$$

$$\varepsilon_{\text{EBS}} = 130 \text{ pm rad}$$
