Differences compared to Light Microscopy

1. It is necessary to analyse samples in a vacuum because airborne contaminants will also scatter electrons. Therefore, samples cannot be visualised in an aqueous solution.

2. High energy electron collisions gives rise to sample damage. Therefore, low electron dosage conditions must be used. This leads to a low signal-to-noise ratio (noisy images).

University of BRISTOL

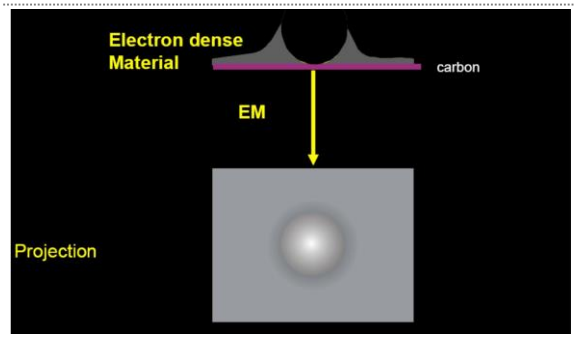
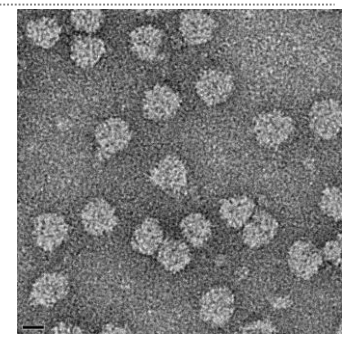
Negative Stain Electron Microscopy





Scale bar : 20 nm uranyl acetate staining

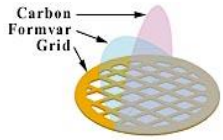
Advantage: nice contrast of the molecules
can be done at room temperature, fast
great for sample quality control

Disadvantage: the resolution is limited by the stain.
staining artefacts, flattening ,
only the envelope is obtained

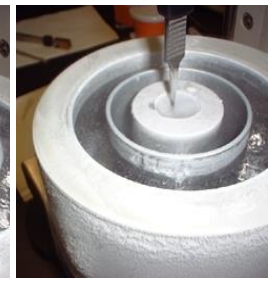
University of BRISTOL

Cryo-EM Sample Preparation

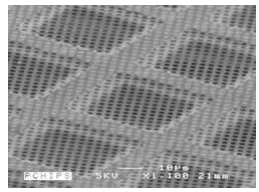
Freezing Grids



3-6 μl of sample (nanomolar concentration) required per grid



Holey carbon film



University of BRISTOL

Vitrification – Cryo-grid preparation: Blotting and Rapid Freezing

- Rapid freezing in liquid ethane leads to formation of vitreous ice.
- Thin ice is required, as the contrast between sample and buffer is low.
- Imaging has to occur at liquid nitrogen temperature to avoid ice contamination.

Cryo-EM Sample Preparation

- Water, or aqueous sample cannot be imaged in the high vacuum of the electron microscope.
- Sample must be frozen and imaged at cryo-temperatures (cooling with liquid nitrogen, -180˚C).
- Ice crystals are black in the electron microscope, so the freezing step has to be very fast -> flash freezing, avoiding ice crystal formation.
- The ice layer must be thin to be able to see the sample in the ice, optimal contrast is achieved when the ice is just a bit thicker than the sample itself. Larger proteins/ complexes are easier to see.

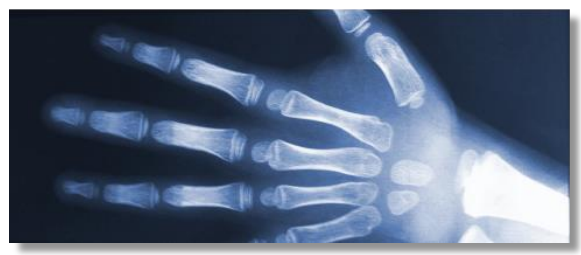
What is a Cryo-EM Image?

It is a projection image.

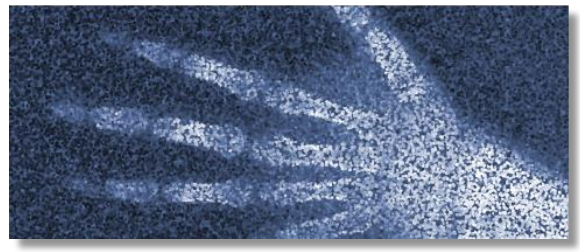


Mark Ian Berger

University of BRISTOL

What is a Cryo-EM Image?

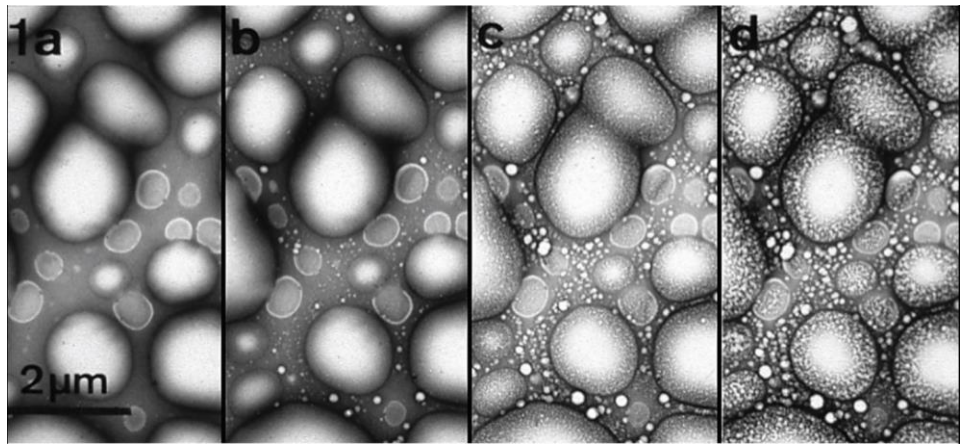
It is a very noisy projection image.



University of BRISTOL

Radiation Damage: the Major Factor that Limits the Attainable Resolution of Cryo-EM Structures

It is noisy because of limited electron dose.



Slide: Andy Hoenger

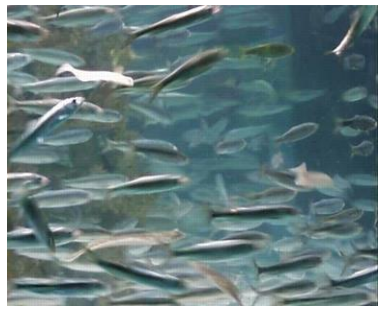
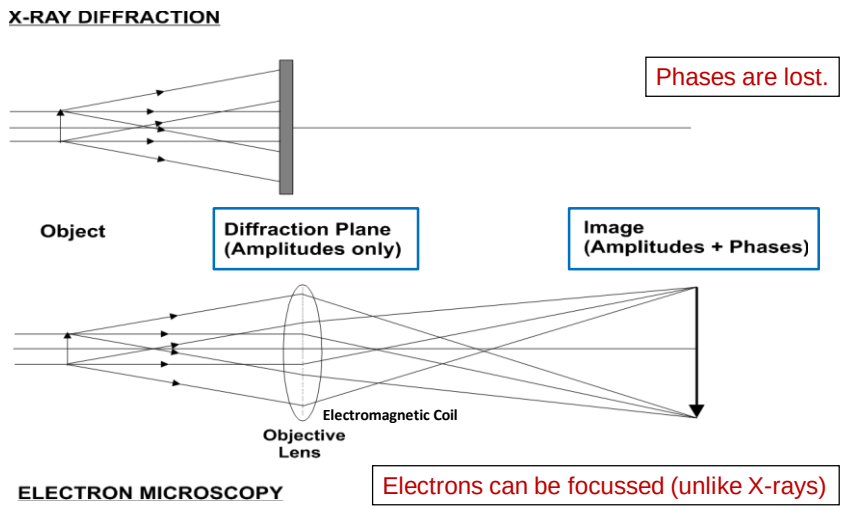
Radiation Damage: the Major Factor that Limits the Attainable Resolution of Cryo-EM Structures

Radiation Damage, another example…



University of BRISTOL

EM Images contain Amplitudes and Phases



University of BRISTOL

Direct Electron Detectors caused the Resolution-Revolution in cryo-EM

Signal to noise ratio is the major challenge in cryo-EM.

New Direct Electron Detectors contain Complementary Metal Oxide Semiconductor (CMOS) chips.

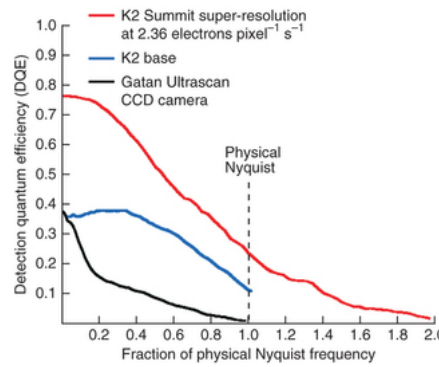
Advantages :

- More sensitive
- Fast
- Super-resolution imaging

Glossary:

Nyquist frequency: The Nyquist Sampling Theorem states that the sampling frequency (Pixel Size) should be at least twice the highest frequency contained in the signal. Small structures are said to have a high frequency.
I.e. to resolve features of 4Å, a pixel size of at least 2Å/px is required.(protein alpha-helical pitch: 5.4Å)

Increased sensitivity:



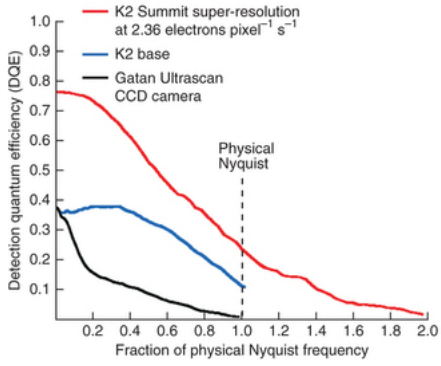
DQE: frequency-dependent measure for signal to noise ratio performance

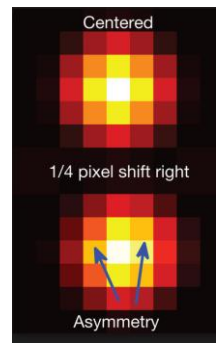
Li et al., Nat. Methods 2013

University of BRISTOL

Direct Electron Detectors – Super Resolution Imaging

Increased sensitivity:





Why does this work? Because the electron dose is low!

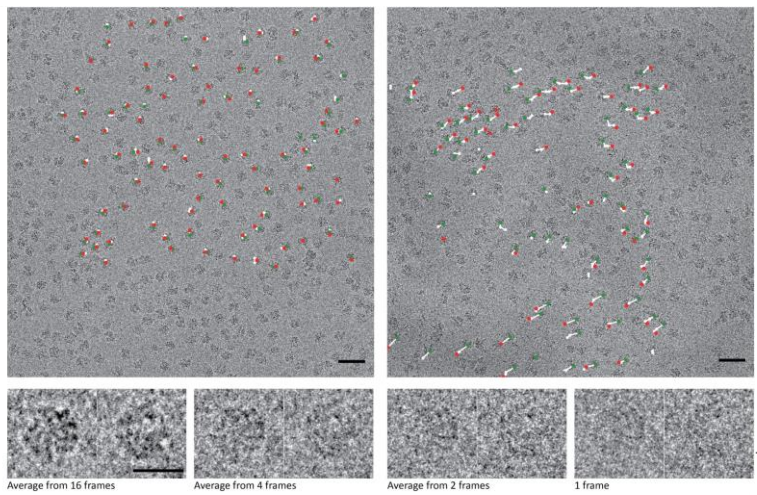
DQE: frequency dependent measure for signal to noise ratio performance

Li et al., Nat. Methods 2013

University of BRISTOL

Motion Correction corrects for stage movement and charging effects (particle movement)

Direct electron detectors record movies, e.g the new K3 camera records 1,500 frames/sec (leading to data storage problems!)



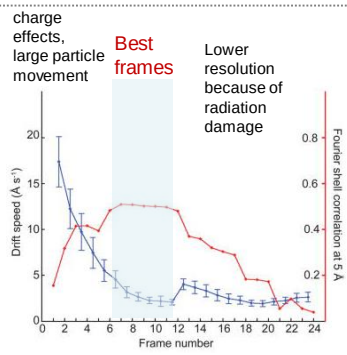
25-fold exaggerated particle movement

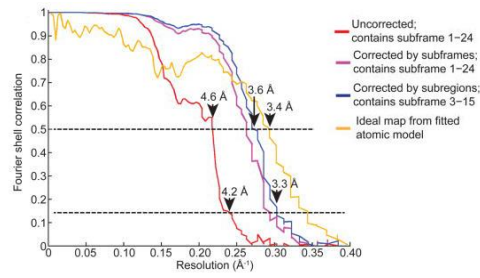
10 Å movements!

Bai et al., Elife 2013

University of BRISTOL

Motion Correction





Motion correction:

- correct for Stage/ Particle movement
- reject frames due to large motion and beam damage

Gain in resolution: 1-2 Å

Li et al., Nat. Methods 2013

University of BRISTOL

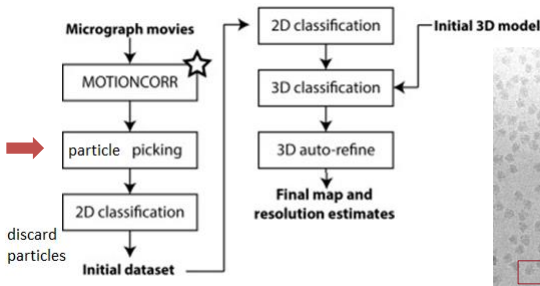
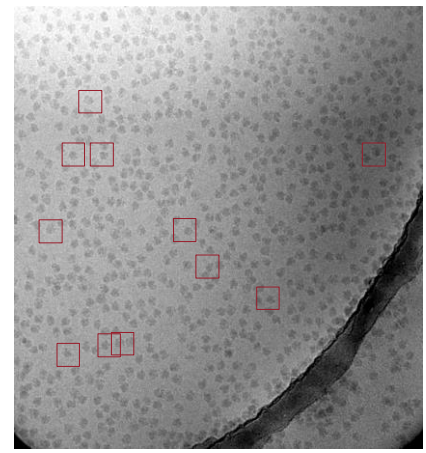
Image Processing Workflow

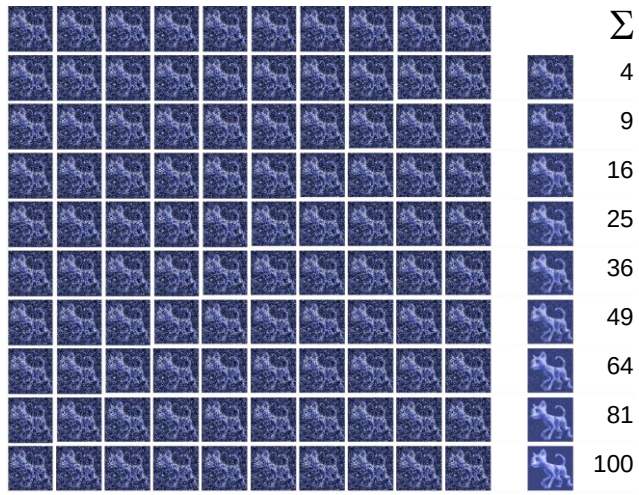




Particle picking:
selection of particle images from a micrograph, resulting in a large data set each having one particle per image.

University of BRISTOL

2D Image Processing: Averaging

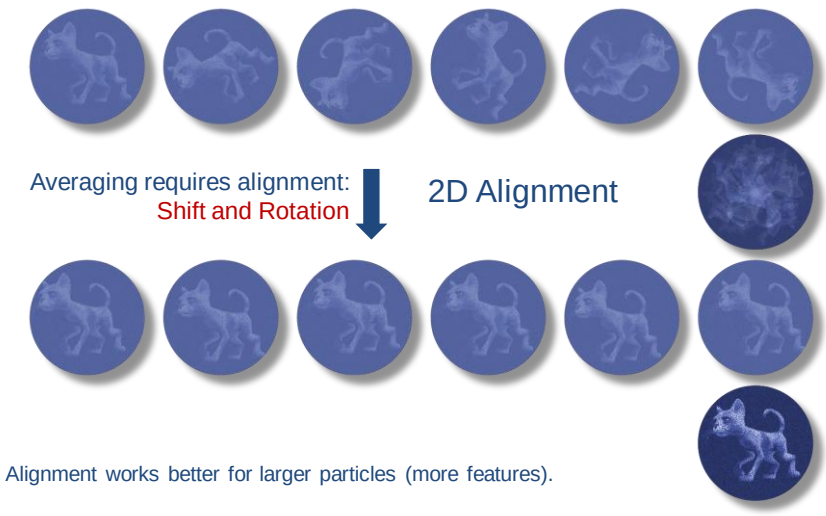


1. We need to average over many images.
2. We need to obtain identical particles (requires computational sorting).

Signal-to-noise ratio growths with √n

University of BRISTOL

Image Processing: Alignment



University of BRISTOL

Single Particle EM – Alignment

Alignment - Averaging works only if:

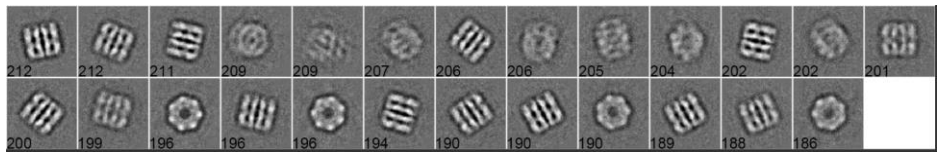
1. All particles are identical.
2. All particles are seen from the same side.

…usually both is not the case.

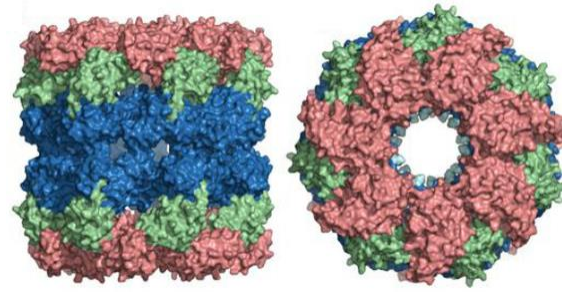
University of BRISTOL

Alignment-Classification-Averaging

GroEL chaperone, 2D class averages



GroEL 3D structure from two views (top & side)

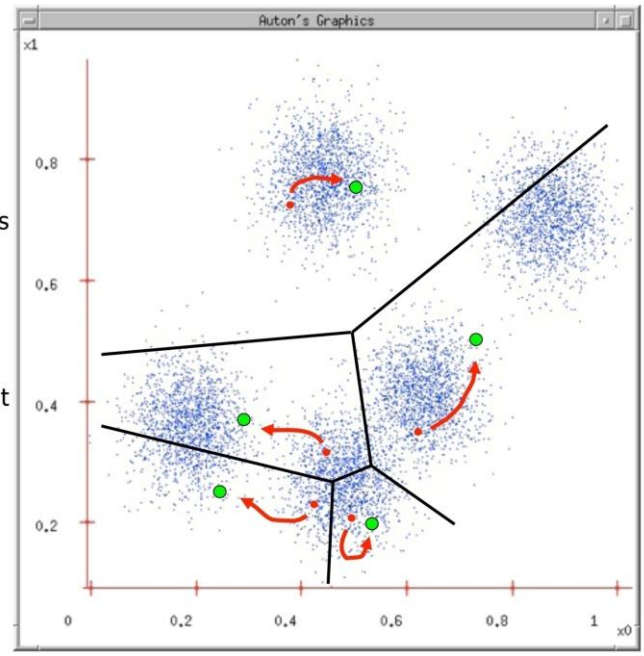


Classification:

- Each image is compared with all other images on a single pixel basis
- Distances between images are related to the similarity between the images
- Clustering identifies similar/close images and follows e.g. k-means algorithms.

K-means

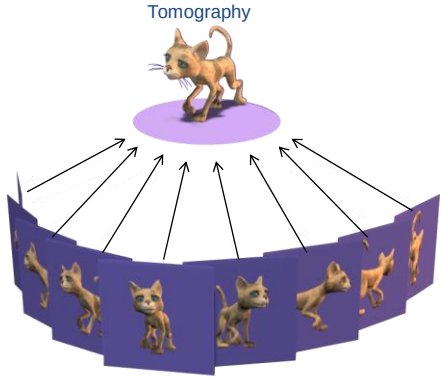
1. Ask user how many clusters they'd like. (e.g. K=5)
2. Randomly guess k cluster Center locations
3. Each datapoint finds out which Center it's closest to.
4. Each Center finds the centroid of the points it owns



University of BRISTOL

We need an 3D Initial Model for structure calculation – e.g. from Tomography or *ab initio* Calculations

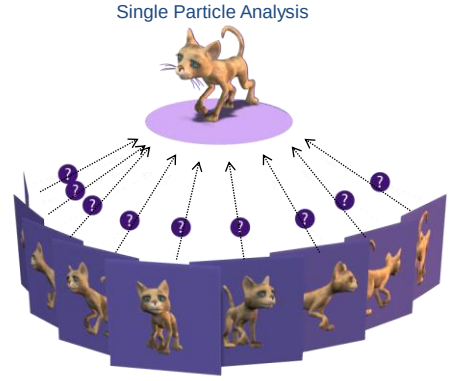
Tomography



Split the electron dose.

Tomography: One object is turned in the electron beam (need to reduce electron dose)
→ many 2D images from one object with known orientation
3D Reconstructions from Tomography have low-resolution and missing information because a 90˚ rotation is not possible.

Single Particle Analysis



Use the max. electron dose for one image.

Many particles with unknown orientation
→ 3D Initial Model required

University of BRISTOL

Workflow: 3D Reconstruction

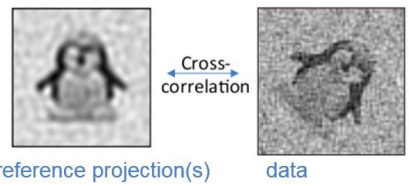
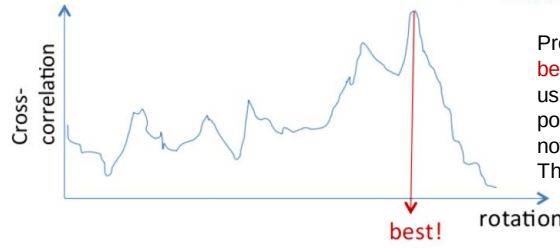
Increased Computational Power allows to use Maximum Likelihood Algorithms

Initial model, 2D



Reference-based Alignment

Rotation and Shift
Determination of the cross-correlation

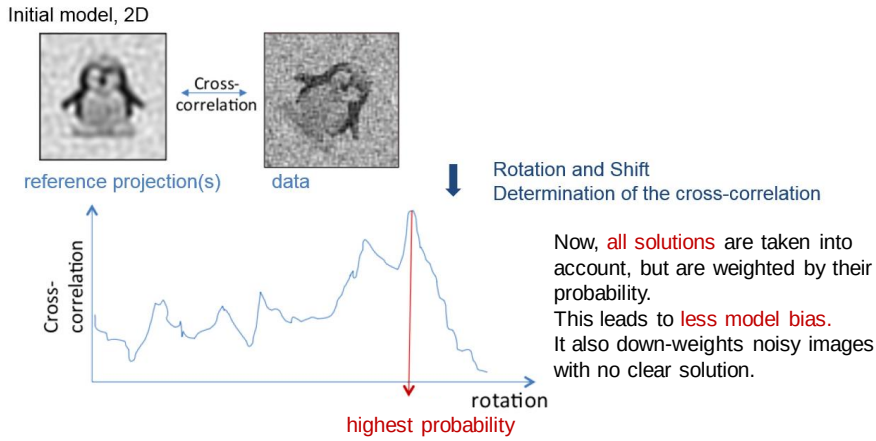


Previously , the solution with the best correlation coefficient was used for alignment; other possible/less likely solutions were not taken into account.
This leads to a strong model bias.

max. cc , real space alignment

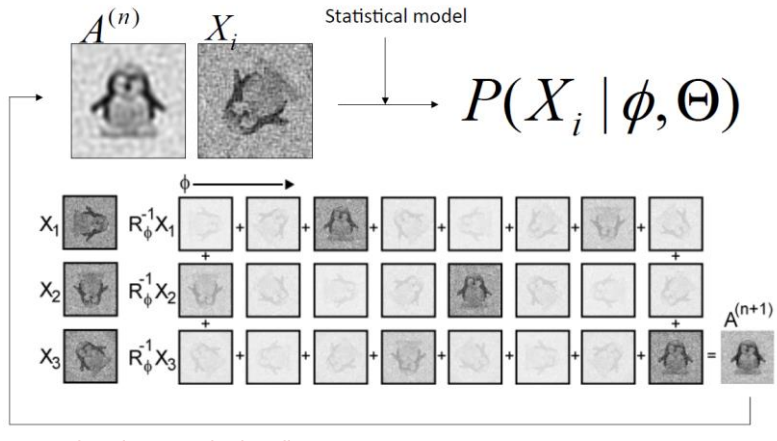
Maximum Likelihood Algorithms are computationally intensive:

… because you go not assign discrete orientations to the data and make hard decisions if the noise in the data does not allow it.



Now, all solutions are taken into account, but are weighted by their probability.
This leads to less model bias.
It also down-weights noisy images with no clear solution.

Maximum Likelihood Algorithms are computationally intensive:

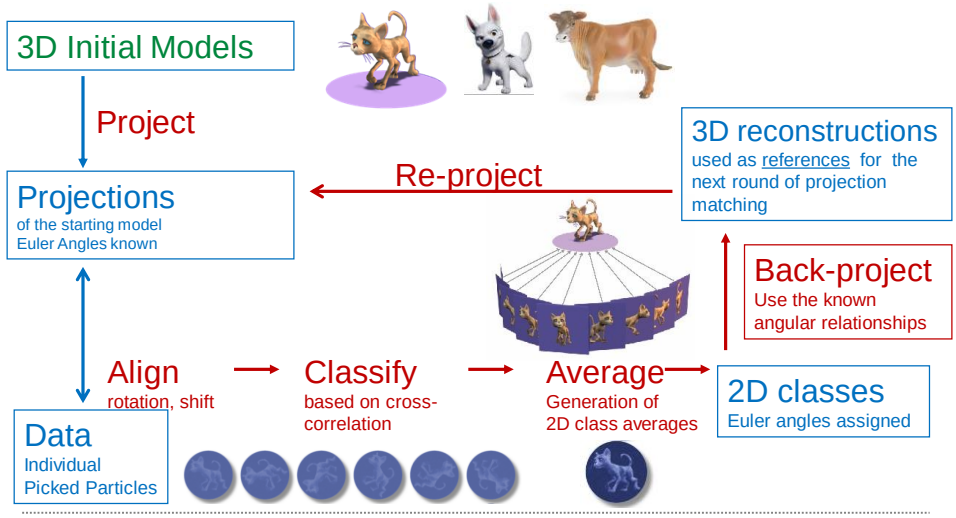


Many iterations required until convergence

Scheres et al., Nat. Protocols 2008

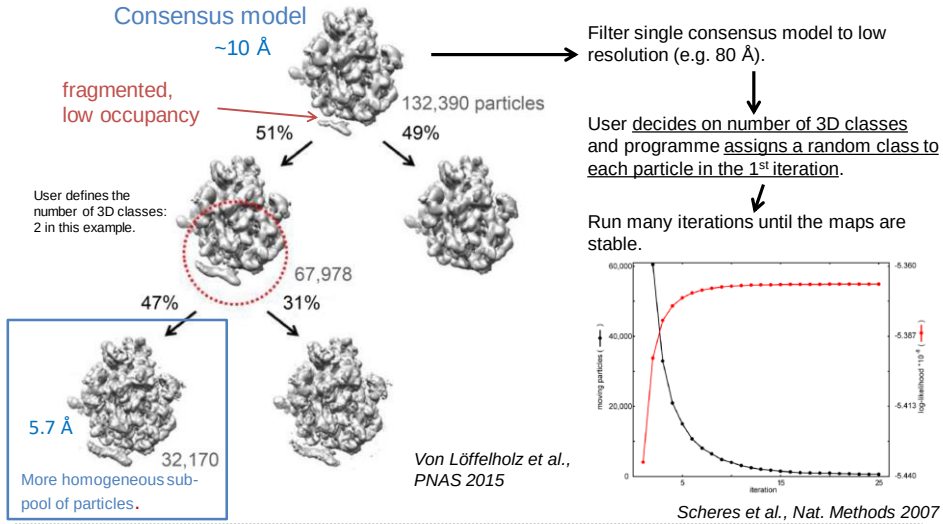
University of BRISTOL

Workflow: 3D Reconstruction, *Dealing with Heterogeneity*



University of BRISTOL

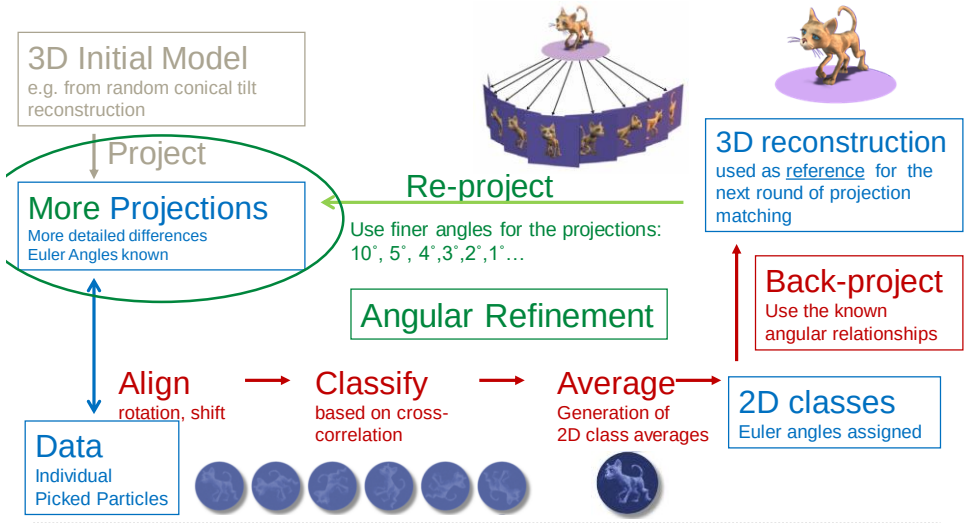
Dealing with Heterogeneity: 3D Classification yields multiple structures



This allows classification without prior knowledge of the differences between the structures present in the data.

University of BRISTOL

3D Refinement, Angular Refinement

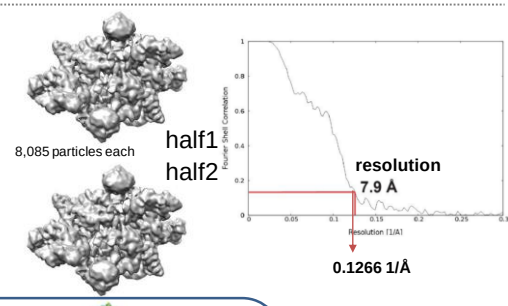


University of BRISTOL

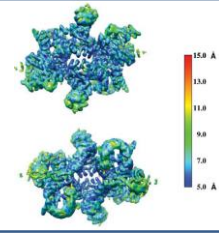
Assessing the Quality of the Structure: Determine the Resolution

Gold standard refinement:

- Split your final particle pool randomly into two.
- Start from the low resolution model and independently refine the two structures.
- Determine (in Fourier space) the correlation at different resolution ranges of the two independent structures = Fourier shell correlation curve.
- A Fourier Shell Correlation Criterion of 0.143 is used to determine the resolution.



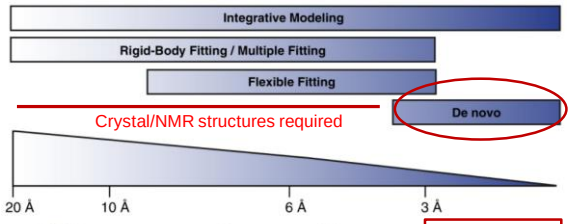
It is important to consider the local resolution: not all parts of a structure are equally well resolved.



Karuppasamy et al., Nature Communications 2017

University of BRISTOL

Interpretation of EM Structures



Up to 20 Å	Up to 9 Å	Up to 6 Å	Up to 4 Å
Conformational changes	Conformational changes	Conformational changes	Conformational changes
Domain boundaries	Domain boundaries	Domain boundaries	Domain boundaries
		Beta sheets	Beta sheets
			Individual beta strands
	Alpha helices	Alpha helices	Alpha helices
			Pitch of alpha helices
		Pitch of RNA helices	Pitch of RNA helices
			Phosphate "bumps"
			Side chains

Current Opinion in Structural Biology

Ideal case, no further information required.

Model can be built *de novo*

Villa & Lasker , CoSB 2016

University of BRISTOL

Atomic Resolution Electron Microscopy

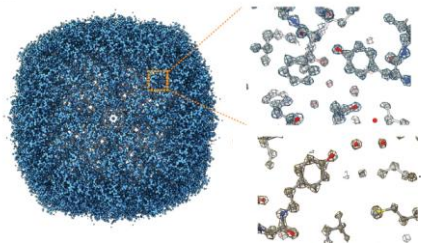
LMB Cambridge team (Nakane et al, *Nature* 2020):

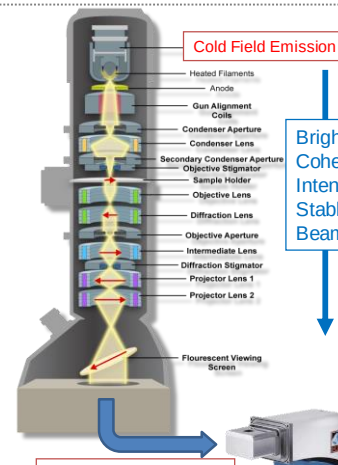
- better electron source (beam with narrow
- energy spread)
- more stable energy filter (removes inelastically scattered electrons more efficiently)
- new generation of DED (faster, more sensitive)
- optical aberration corrections during image processing

MPI team (Yip et al, *Nature* 2020):

- Home-build microscope with advanced electron-optical devices: monochromator and spherical aberration corrector

-> more coherent electron beam and reduce optical aberrations.





Cold Field Emission Gun

Bright, Coherent, Intense, Stable Beam

Energy Filter
(elastically scattered electrons only)

Direct Electron Detector
K3 camera 1,500 full frames per second; ~4x faster

University of BRISTOL

Summary

Advantages:

1. The sample is studied in solution, at near-native conditions
2. Small amount of sample required
3. No crystallisation necessary
4. It is possible to study large macromolecular complexes and membrane proteins, i.e. samples which are difficult to crystallise
5. Computational sorting allows insights into the dynamics of macromolecular machines: more than one structure can be solved from one sample, revealing different functional states.
6. One or several structures can be solved from samples which are not completely 'pure', provided the complex of interest can be identified and computationally purified from the contaminations.

Disadvantages, Limitations and Problems:

1. Low intrinsic contrast of the sample
2. Radiation damage > low signal-to-noise ratio in the images
3. One image per particle – very large data sets required to amplify the signal
4. Determining and dealing with heterogeneity (dynamics, partial complexes, contaminations) is computationally intensive and often limits the resolution of the structure. The basic assumption that the 'sample is homogenous' is usually not correct due to the heterogeneity.
5. Anisotropy resulting from missing views are a common problem, often due to interaction of particles with the air-water interface.
