Surface structure of (La,Sr)CoO₃ film under electrochemical conditions

Perovskite oxides exhibit various functionalities. In the current social circumstances, their catalytic functionality is one of the most significant characteristics. Some of Co oxides are known as high performance water splitting catalysts. Here, we report in-situ surface x-ray diffraction measurement of (La,Sr)CoO₃ films grown on Nb doped SrTiO₃ (001) substrates.

Experiments were done at BL-3A and 4C of the Photon Factory, KEK, Japan. The (La,Sr)CoO₃ films were grown on atomically flat SrTiO₃ substrate by pulsed laser deposition. Measurements were done in vacuum and under electrochemical conditions (0.1M KOH aq., electric potential in the range of $\pm 0.7V$ vs Ag/AgCl).

In-vacuum structure was analyzed with our Bayesian inference software CTR-structure[1]. In the vacuum condition, the surface/interface structure has 3.84 Å of the out-of-plane lattice parameter, and Sr condensation at the surface was also observed. In the electrochemical conditions, we obtained clear voltage dependence of the CTR intensity at several Q positions. Detailed analysis is now under way.
